Abstract

We give a polynomial-time approximation scheme for the unique unit-square coverage problem: given a set of points and a set of axis-parallel unit squares, both in the plane, we wish to find a subset of squares that maximizes the number of points contained in exactly one square in the subset. Erlebach and van Leeuwen (2008) introduced this problem as the geometric version of the unique coverage problem, and the best approximation ratio by van Leeuwen (2009) before our work was 2. Our scheme can be generalized to the budgeted unique unit-square coverage problem, in which each point has a profit, each square has a cost, and we wish to maximize the total profit of the uniquely covered points under the condition that the total cost is at most a given bound.

1. Introduction

Let \mathcal{P} be a set of points and \mathcal{D} a set of axis-parallel unit squares,¹ both in the plane \mathbb{R}^2 . For a subset $\mathcal{C} \subseteq \mathcal{D}$ of unit squares, we say that a point $p \in \mathcal{P}$ is *uniquely covered* by \mathcal{C} if there is exactly one square in \mathcal{C} containing p . In the *unique unit-square coverage problem*, we are given a pair $\langle \mathcal{P}, \mathcal{D} \rangle$ of a set \mathcal{P} of

¹Throughout this paper, a unit square is of side length one and is closed, thus contains the boundary.

Figure 1: (a) An instance $\langle \mathcal{P}, \mathcal{D} \rangle$ of the unique unit-square coverage problem and (b) an optimal solution to $\langle \mathcal{P}, \mathcal{D} \rangle$, where each square in the optimal solution is hatched and each uniquely covered point is drawn as a white circle.

1 points and a set \mathcal{D} of axis-parallel unit squares as input, and we are asked to
 2 find a subset $\mathcal{C} \subseteq \mathcal{D}$ that maximizes the number of points uniquely covered by
 3 \mathcal{C} . An instance is shown in Figure 1(a), and an optimal solution to this instance
 4 is illustrated in Figure 1(b).

5 In a more general setting, in addition to an instance $\langle \mathcal{P}, \mathcal{D} \rangle$ of the unique
 6 unit-square coverage problem, we are given a non-negative real number B , called
 7 the *budget*, a non-negative real number $\text{profit}(p)$ for each point $p \in \mathcal{P}$, called the
 8 *profit* of p , and a non-negative real number $\text{cost}(S)$ for each square $S \in \mathcal{D}$,
 9 called the *cost* of S . In the *budgeted unique unit-square coverage problem*, we
 10 are asked to find a subset $\mathcal{C} \subseteq \mathcal{D}$ of total cost at most B such that the total
 11 profit of points in \mathcal{P} uniquely covered by \mathcal{C} is maximized. The unique unit-
 12 square coverage problem is a specialization of the budgeted unique unit-square
 13 coverage problem. To see this, set $\text{profit}(p) = 1$ for all $p \in \mathcal{P}$, $\text{cost}(S) = 0$ for all
 14 $S \in \mathcal{D}$, and $B = 0$.

15 1.1. Past work and motivation

16 Demaine et al. [7] formulated the non-geometric unique coverage problem in
 17 more general setting. They gave a polynomial-time $O(\log n)$ -approximation
 18 algorithm² for the non-geometric unique coverage problem, where n is the number
 19 of elements (in the geometric version, n corresponds to the number of points).
 20 Guruswami and Trevisan [12] studied the same problem and its generaliza-
 21 tion, which they called the 1-in- k SAT. The unique coverage problem appears
 22 in several situations. The previous papers [7, 12] provide a connection with
 23 unlimited-supply single-minded envy-free pricing and the maximum cut prob-
 24 lem. For details, see their papers.

25 The parameterized complexity of the unique coverage problem has also been
 26 studied by Misra et al. [19].

²For notational convenience, throughout the paper, we say that an algorithm for a max-
 imization problem is α -approximation if it returns a solution with the objective value APX
 such that $\text{OPT} \leq \alpha \text{APX}$, where OPT is the optimal objective value, and hence $\alpha \geq 1$.

1 Motivated by applications from wireless networks, Erlebach and van Leeuwen
2 [9] studied the geometric versions of the unique coverage problem especially on
3 unit disks. In the context of wireless networks, each point corresponds to a
4 customer location, and the center of each disk corresponds to a place where
5 the provider can build a base station. If several base stations cover a certain
6 customer location, then the resulting interference might cause this customer to
7 receive no service at all. Ideally, each customer should be serviced by exactly one
8 base station. This situation corresponds to the unique unit-disk coverage problem.
9 They showed that the problem on unit disks is strongly NP-hard, and gave
10 a polynomial-time 18-approximation algorithm; for the budgeted unique unit-
11 disk coverage problem, they provided a polynomial-time $(18 + \varepsilon)$ -approximation
12 algorithm for any fixed constant $\varepsilon > 0$ [9].

13 The unique unit-square coverage problem is an ℓ_∞ variant (or an ℓ_1 variant)
14 of the unique unit-disk coverage problem. Erlebach and van Leeuwen
15 [9] introduced the budgeted unique unit-square coverage problem, and gave a
16 polynomial-time $(4 + \varepsilon)$ -approximation algorithm for any fixed constant $\varepsilon > 0$.
17 Later, van Leeuwen [21] gave a proof that the problem on unit squares is also
18 strongly NP-hard, and improved the approximation ratio to $2 + \varepsilon$.

19 Optimization problems on axis-parallel unit squares and unit disks have been
20 thoroughly studied since Huson and Sen [15]. A seminal paper by Hochbaum
21 and Maass [13] established the shifting strategy, which has been used to give
22 a polynomial-time approximation scheme (PTAS) for a lot of problems on unit
23 squares and unit disks (see [14] for example). However, some problems such
24 as coloring [6] and dispersion [11] (see also [8]) are APX-hard already for unit
25 disks. The unique coverage problem is one among the problems for which we
26 know the NP-hardness, but neither APX-hardness nor a PTAS was known. The
27 existence of a PTAS for unit squares has been asked by van Leeuwen [21].

28 In a sister paper, we exhibit a polynomial-time approximation algorithm for
29 the unique unit-disk coverage problem with approximation ratio $2 + 4/\sqrt{3} + \varepsilon$
30 ($< 4.3095 + \varepsilon$), where $\varepsilon > 0$ is any fixed constant [16].

31 After the conference version [17] of this paper was published, Chan and Hu
32 [4] gave another PTAS for the unique unit-square coverage problem, which is,
33 as they claim, “simpler to describe” than ours.

34 *1.2. Contribution of the paper*

35 In this paper, we give the first PTAS for the unique unit-square coverage
36 problem, and hence we improve the approximation ratio to $1 + \varepsilon$ for any fixed
37 constant $\varepsilon > 0$. The algorithm is generalized to give a PTAS for the budgeted
38 unique unit-square coverage problem, too.

39 We employ the well-known shifting strategy, developed by Baker [1] and
40 applied to the geometric problems by Hochbaum and Maass [13]. Namely, we
41 partition the whole plane into “ribbons” of height one, and delete the points in
42 every $1 + \lceil 1/\varepsilon \rceil$ ribbons. Then, the instance is divided into several subinstances
43 in which all points lie in a rectangle of height $\lceil 1/\varepsilon \rceil$. We compute optimal
44 solutions to such subinstances, and take their union. The best among all choices

1 of possible deletions will be a $(1 + \varepsilon)$ -approximate solution. On the other hand,
2 van Leeuwen [21] was only able to solve a subinstance in a rectangle of height
3 one, and thus only gave a 2-approximation since he removed the points in every
4 two ribbons. A similar approach was used to give a PTAS for the weighted unit-
5 square cover problem [10], but the adaptation to the unique coverage problem
6 is by far more involved, as seen in this paper.

7 By the strong NP-hardness, we can conclude that there is no fully
8 polynomial-time approximation scheme unless $P = NP$ [20]; in this sense, a
9 PTAS is the best approximation algorithm for the problem.

10 An extended abstract of this paper has been presented at the 13th Scandi-
11 navian Symposium and Workshops on Algorithm Theory (SWAT 2012) [17].

12 2. Main result

13 The following is the main result of the paper.

14 **Theorem 2.1.** *For any fixed constant $\varepsilon > 0$, there is a polynomial-time $(1 + \varepsilon)$ -*
15 *approximation algorithm for the unique unit-square coverage problem.*

16 We are given an instance $\langle \mathcal{P}, \mathcal{D} \rangle$. Our algorithm consists of two parts. In the
17 first part, we partition the plane into horizontal ribbons of height one, and show
18 in Section 2.2 that if there is a polynomial-time exact algorithm for the problem
19 restricted to a constant number of ribbons, then the problem on $\langle \mathcal{P}, \mathcal{D} \rangle$ admits a
20 PTAS. As the second part, Section 3 will be devoted to such a polynomial-time
21 exact algorithm.

22 2.1. Preliminaries

23 A rectangle is *axis-parallel* if its boundary consists of horizontal and vertical
24 line segments. Let R_W be an (unbounded) axis-parallel rectangle of width W
25 and height ∞ which properly contains all points in \mathcal{P} and all unit squares in \mathcal{D} .
26 We fix the origin of the coordinate system on the left vertical boundary of R_W .
27 For a square $S \in \mathcal{D}$, we define the (x, y) -coordinates of S as the coordinates
28 of the top right corner of S ; we denote by $x(S)$ the x -coordinate of S , and by
29 $y(S)$ the y -coordinate of S . We can assume without loss of generality that a
30 given set of squares is in general position, which means that, **for the purposes**
31 **of this paper**, no horizontal (or vertical) side of a square is on the same line as
32 the horizontal (resp., vertical) side of another square; otherwise, we can scale
33 and translate the squares in polynomial time so that this condition is satisfied
34 [21].

35 We partition the rectangle R_W into *ribbons* $R_i = [0, W] \times [i, i + 1)$, $i \in \mathbb{Z}$,
36 that is, each ribbon is a rectangle of width W and height one. We may assume
37 without loss of generality that no point in \mathcal{P} and no horizontal side of a square in
38 \mathcal{D} is on the same line as the horizontal boundary of any ribbon [21]. Therefore,
39 every unit square of side length one intersects exactly two (consecutive) ribbons.
40 We may assume that each ribbon in R_W contains at least one point in \mathcal{P} and
41 intersects at least one square in \mathcal{D} ; otherwise, we can simply ignore such ribbons.

Figure 2: The set R_W^j of ribbons for each $j \in \{0, \dots, k\}$ when $k = 4$.

1 We thus deal with only a polynomial number of ribbons. Let R_1, R_2, \dots, R_t be
 2 the ribbons in R_W ordered from bottom to top.

3 For a set G of ribbons, we denote by $\mathcal{P} \cap G$ the set of all points in \mathcal{P} contained
 4 in the ribbons in G . For a point set \mathcal{P} and a square set $\mathcal{C} \subseteq \mathcal{D}$, we denote by
 5 $\text{profit}(\mathcal{P}, \mathcal{C})$ the number of points in \mathcal{P} that are uniquely covered by \mathcal{C} .

6 *2.2. Restricting the problem to a constant number of ribbons*

7 As the first part of our algorithm, we give the following lemma, by applying
 8 the well-known shifting strategy [9, 13].

9 **Lemma 2.2.** *Let $k = \lceil 1/\varepsilon \rceil$ be a fixed constant, and suppose that we can obtain
 10 an optimal solution to $\langle \mathcal{P} \cap G, \mathcal{D} \rangle$ in polynomial time for every set G consisting
 11 of at most k ribbons. Then, we can obtain a $(1 + \varepsilon)$ -approximate solution to
 12 $\langle \mathcal{P}, \mathcal{D} \rangle$ in polynomial time.*

13 **PROOF.** For an index $j \in \{0, \dots, k\}$, let R_W^j be the set of ribbons obtained
 14 from R_W by deleting the ribbons R_i , $1 \leq i \leq t$, if and only if $i \equiv j \pmod{k+1}$,
 15 as illustrated in Figure 2. We regard the remaining (at most) k consecutive
 16 ribbons in R_W^j as forming one *group*. Then, those groups have pairwise distance
 17 more than one, and hence no square (with side length one) can cover points in
 18 two distinct groups. Therefore, we can independently solve the problem on
 19 $\langle \mathcal{P} \cap G, \mathcal{D} \rangle$, where G is a group in R_W^j . (Indeed, it suffices to consider the
 20 squares in \mathcal{D} which intersect the group G .) Combining the optimal solutions for
 21 all groups in R_W^j , we obtain an optimal solution $\mathcal{C}^j \subseteq \mathcal{D}$ to $\langle \mathcal{P} \cap R_W^j, \mathcal{D} \rangle$. As
 22 our approximate solution $\mathcal{C}_A \subseteq \mathcal{D}$ to $\langle \mathcal{P}, \mathcal{D} \rangle$, we choose the best one from \mathcal{C}^j ,
 23 $0 \leq j \leq k$, and hence we have

$$\text{profit}(\mathcal{P}, \mathcal{C}_A) \geq \max_{0 \leq j \leq k} \text{profit}(\mathcal{P} \cap R_W^j, \mathcal{C}^j). \quad (1)$$

24 Clearly, we can obtain the approximate solution \mathcal{C}_A in polynomial time if the
 25 problem on $\langle \mathcal{P} \cap G, \mathcal{D} \rangle$ for each group G can be optimally solved in polynomial
 26 time.

27 We now show that the above algorithm is a $(1 + \varepsilon)$ -approximation to the
 28 original instance $\langle \mathcal{P}, \mathcal{D} \rangle$. Consider an arbitrary optimal solution $\mathcal{C}^* \subseteq \mathcal{D}$ to
 29 $\langle \mathcal{P}, \mathcal{D} \rangle$. The shifting strategy [13] with respect to the index j implies that there
 30 exists an index $j^* \in \{0, 1, \dots, k\}$ such that

$$\frac{k}{k+1} \text{profit}(\mathcal{P}, \mathcal{C}^*) \leq \text{profit}(\mathcal{P} \cap R_W^{j^*}, \mathcal{C}^*).$$

1 Remember that \mathcal{C}^{j^*} is an optimal solution to $\langle \mathcal{P} \cap R_W^{j^*}, \mathcal{D} \rangle$. Therefore, we have
 2 $\text{profit}(\mathcal{P} \cap R_W^{j^*}, \mathcal{C}^*) \leq \text{profit}(\mathcal{P} \cap R_W^{j^*}, \mathcal{C}^{j^*})$. Since $k = \lceil 1/\varepsilon \rceil$, we thus have

$$\text{profit}(\mathcal{P}, \mathcal{C}^*) \leq \left(1 + \frac{1}{k}\right) \cdot \text{profit}(\mathcal{P} \cap R_W^{j^*}, \mathcal{C}^*) \leq (1 + \varepsilon) \cdot \text{profit}(\mathcal{P} \cap R_W^{j^*}, \mathcal{C}^{j^*}).$$

3 By Eq. (1), we thus have $\text{profit}(\mathcal{P}, \mathcal{C}^*) \leq (1 + \varepsilon)\text{profit}(\mathcal{P}, \mathcal{C}_A)$, as required. \square

4 **3. Algorithm for a constant number of ribbons**

5 Together with Lemma 2.2, the following lemma completes the proof of The-
 6 orem 2.1.

7 **Lemma 3.1.** *The unique unit-square coverage problem on $\langle \mathcal{P} \cap G, \mathcal{D} \rangle$ can be*
 8 *optimally solved in polynomial time for a set G consisting of at most k ribbons,*
 9 *where k is a constant.*

10 The proof of Lemma 3.1 is constructive, namely, we give such an algorithm.
 11 In this section, we introduce Lemmas 3.3 and 3.5, which are key lemmas of this
 12 paper, and give the whole algorithm based on them; Section 4 gives the proofs of
 13 the two key lemmas. The proof of Lemma 3.1 will be based on the key lemmas.

14 *3.1. Basic idea of our algorithm*

15 Our algorithm employs a dynamic programming approach based on the line-
 16 sweep paradigm. Namely, we look at points and squares from left to right, and
 17 extend the uniquely covered region sequentially. However, adding one square S
 18 at the rightmost position can influence a lot of squares that were already chosen,
 19 and can change the situation drastically (we say that S *influences* a square S' if
 20 the region uniquely covered by S' changes after the addition of S). We therefore
 21 need to keep track of the squares that are possibly influenced by a newly added
 22 square. Unless the number of those squares is bounded by some constant (or
 23 the logarithm of the input size), this approach cannot lead to a polynomial-time
 24 algorithm. Unfortunately, new squares may influence arbitrarily many (i.e., a
 25 super-constant or super-logarithmic number of) squares.

26 Instead of adding a square at the rightmost position, we add a square S such
 27 that the number of squares that were already chosen and influenced by S can be
 28 bounded by a constant. Lemmas 3.3 and 3.5 state that we can do this for any
 29 set of squares, as long as a trivial condition for the square set to be an optimal
 30 solution is satisfied. Furthermore, such a square can be found in polynomial
 31 time.

32 *3.2. Basic definitions*

33 We may assume without loss of generality that the set G consists of con-
 34 secutive ribbons, forming a group; otherwise we can simply solve the problem
 35 for each group, because those groups have pairwise distance more than one.
 36 Suppose that G consists of k consecutive ribbons $R_{j+1}, R_{j+2}, \dots, R_{j+k}$ in R_W ,

Figure 3: A set \mathcal{C} of squares in \mathcal{D}_i , together with $A_1(\mathcal{C})$ (gray), the upper envelope (red) and the lower envelope (blue). The dotted lines show the lower boundaries of R_{i-1} , R_i and R_{i+1} .

1 ordered from bottom to top, for some integer j . If a square can cover points in
 2 $\mathcal{P} \cap G$, then it is totally included in ribbons $R_j, R_{j+1}, \dots, R_{j+k+1}$. For nota-
 3 tional convenience, in the remainder of this section, we assume $j = 0$ without
 4 loss of generality. Note that the two ribbons R_0 and R_{k+1} are not in G .

5 Since no horizontal side of a square is on the same line as the horizontal
 6 boundary of any ribbon, if a square in \mathcal{D} intersects G , then it intersects the lower
 7 boundary of exactly one ribbon R_i , $i \in \{1, \dots, k+1\}$. For each $i \in \{1, \dots, k+1\}$,
 8 we denote by $\mathcal{D}_i \subseteq \mathcal{D}$ the subset of all squares in \mathcal{D} intersecting the lower
 9 boundary of R_i . Note that the square sets $\mathcal{D}_1, \mathcal{D}_2, \dots, \mathcal{D}_{k+1}$ form a partition of
 10 the squares intersecting G . No square in \mathcal{D}_i intersects any square in \mathcal{D}_j with
 11 $j \leq i-2$ or $j \geq i+2$. Furthermore, if a square S_i in \mathcal{D}_i intersects a square S_{i+1}
 12 in \mathcal{D}_{i+1} (or a square S_{i-1} in \mathcal{D}_{i-1}), then the intersection $S_i \cap S_{i+1}$ must be in
 13 R_i (resp., $S_{i-1} \cap S_i$ must be in R_{i-1}).

14 For a square set $\mathcal{C} \subseteq \mathcal{D}$, let $A_0(\mathcal{C})$, $A_1(\mathcal{C})$, $A_2(\mathcal{C})$ and $A_{\geq 3}(\mathcal{C})$ be the areas
 15 covered by no square, exactly one square, exactly two squares, and three or
 16 more squares in \mathcal{C} , respectively. Then, each point contained in the area $A_1(\mathcal{C})$
 17 is uniquely covered by \mathcal{C} .

18 3.3. Properties on square subsets of \mathcal{D}_i

19 In this subsection, we deal with squares only in a set $\mathcal{C} \subseteq \mathcal{D}_i$ and the region
 20 uniquely covered by them. Of course, squares in $\mathcal{D}_{i-1} \cup \mathcal{D}_{i+1}$ may influence
 21 squares in \mathcal{C} ; this difficulty will be discussed in Section 3.5.

22 3.3.1. Upper and lower envelopes

23 Let $\mathcal{C} \subseteq \mathcal{D}_i$ be a square set. Since \mathcal{C} is in general position, we can partition
 24 the boundary of the closure of $A_1(\mathcal{C})$ into two types: The boundary between
 25 $A_0(\mathcal{C})$ and $A_1(\mathcal{C})$; and that between $A_1(\mathcal{C})$ and $A_2(\mathcal{C})$. We call the former the
 26 *union boundary* of \mathcal{C} . In Figure 3, the union boundary of \mathcal{C} is illustrated as
 27 (red or blue) thick lines. We call the union boundary in R_i (or R_{i-1}) the *upper*
 28 (resp., *lower*) *envelope* of \mathcal{C} . We say that a square S forms the boundary of an
 29 area A if a portion of a side of S appears on the boundary of the closure of
 30 A . Let $UE(\mathcal{C})$ and $LE(\mathcal{C})$ be the sequences of squares that form the upper and
 31 lower envelopes of \mathcal{C} , from right to left, respectively. Note that a square $S \in \mathcal{C}$
 32 may appear in both $UE(\mathcal{C})$ and $LE(\mathcal{C})$. An example is shown in Figure 3.

33 Consider an arbitrary optimal solution $\mathcal{C}^* \subseteq \mathcal{D}_i$ to $\langle \mathcal{P} \cap (R_{i-1} \cup R_i), \mathcal{D}_i \rangle$. If
 34 there is a square $S \in \mathcal{C}^*$ contained in the union of $\mathcal{C}^* \setminus \{S\}$, i.e., $S \cap A_1(\mathcal{C}^*) = \emptyset$,

1 then we can simply remove it from \mathcal{C}^* without losing the optimality. Thus,
 2 hereafter we deal with a square set $\mathcal{C} \subseteq \mathcal{D}_i$ such that every square S in \mathcal{C} forms
 3 the union boundary of \mathcal{C} , that is, $S \in UE(\mathcal{C})$ or $S \in LE(\mathcal{C})$ holds. (Note that
 4 some square $S \in \mathcal{C}$ may satisfy both $S \in UE(\mathcal{C})$ and $S \in LE(\mathcal{C})$.) This property
 5 enables us to extend the upper and lower envelopes sequentially.

6 3.3.2. Top squares and the key lemma

7 When we add a “new” square S to the current square set $\mathcal{C} \setminus \{S\}$, we need
 8 to know the symmetric difference of $A_1(\mathcal{C})$ and $A_1(\mathcal{C} \setminus \{S\})$: The area $A_1(\mathcal{C}) \setminus$
 9 $A_1(\mathcal{C} \setminus \{S\}) \subseteq A_1(\mathcal{C})$ is the uniquely covered area obtained by adding S , and the
 10 area $A_1(\mathcal{C} \setminus \{S\}) \setminus A_1(\mathcal{C}) \subseteq A_2(\mathcal{C})$ is the non-uniquely covered area due to the
 11 addition of S . However, it suffices to know $A_1(\mathcal{C} \setminus \{S\}) \setminus A_1(\mathcal{C})$ and its boundary
 12 since the boundary of $A_1(\mathcal{C}) \setminus A_1(\mathcal{C} \setminus \{S\})$ is formed only by S and the squares
 13 forming the boundary of $A_1(\mathcal{C} \setminus \{S\}) \setminus A_1(\mathcal{C})$.

14 For a square S in a set $\mathcal{C} \subseteq \mathcal{D}$, let $\Delta(\mathcal{C}, S)$ be the set of all squares in
 15 \mathcal{C} that form the boundary of $A_1(\mathcal{C} \setminus \{S\}) \setminus A_1(\mathcal{C})$. An example is shown in
 16 Figure 4. Clearly, every square in $\Delta(\mathcal{C}, S)$ has non-empty intersection with S .
 17 As we mentioned in Section 3.1, $\Delta(\mathcal{C}, S)$ may contain arbitrarily many (i.e., a
 18 super-constant or super-logarithmic number of) squares if we simply choose the
 19 rightmost square S in \mathcal{C} .

20 The plan is as follows. (The formal definitions will be given later.)

- 21 • For each square set $\mathcal{C} \subseteq \mathcal{D}_i$, we canonically identify a subset of “rightmost”
 22 squares, which we call *top squares*. Such a set of top squares of \mathcal{C} has the
 23 following property: there always exists a top square S of \mathcal{C} such that
 24 $\Delta(\mathcal{C}, S)$ only contains top squares of \mathcal{C} . Such a square S will be called
 25 *stable* in the set of top squares.
- 26 • Some square sets may have the same set of top squares. This defines a
 27 preimage: given a set \mathcal{F} of squares, we identify the family of all square sets
 28 contained in \mathcal{D}_i such that their sets of top squares are equal to \mathcal{F} . This
 29 family will be denoted by $\mathfrak{C}_i(\mathcal{F})$. A candidate \mathcal{F} of the set of top squares
 30 will be called a *feasible* set. **Note that $\mathfrak{C}_i(\mathcal{F}) \neq \emptyset$ when \mathcal{F} is feasible.**
- 31 • To perform the dynamic programming, we only maintain a value for every
 32 feasible set \mathcal{F} . The dynamic programming computes the value for \mathcal{F} “from
 33 left to right.” To obtain the value for \mathcal{F} , we look at a stable square S in \mathcal{F}
 34 and delete it from each square set \mathcal{C} in $\mathfrak{C}_i(\mathcal{F})$. Then, $\mathcal{C} \setminus \{S\}$ has another
 35 set of top squares for which the value was already computed in the course
 36 of dynamic programming. Since $\Delta(\mathcal{C}, S)$ only contains top squares of \mathcal{C} ,
 37 we can also compute the **area uniquely covered** by $\Delta(\mathcal{C}, S)$ in polynomial
 38 time. This enables us to calculate the value for \mathcal{F} , and we can complete
 39 our dynamic-programming computation.

40 Following this plan, we first give definitions.

41 For a square set $\mathcal{C} \subseteq \mathcal{D}_i$, a square $S \in \mathcal{C}$ is called a *top square* of \mathcal{C} if one of
 42 the following conditions (i)–(iv) holds:

Figure 4: The gray region shows $A_1(\mathcal{C} \setminus \{S\}) \setminus A_1(\mathcal{C})$ for the thick square S .

Figure 5: An example of top squares. The (blue) thick squares are top squares, and the numbers correspond to the conditions in the definition.

- 1 (i) S is one of the six rightmost squares of $UE(\mathcal{C})$;
- 2 (ii) S is one of the six rightmost squares of $LE(\mathcal{C})$;
- 3 (iii) S is one of the two rightmost squares of $UE(LE(\mathcal{C}) \setminus UE(\mathcal{C}))$;
- 4 (iv) S is one of the two rightmost squares of $LE(UE(\mathcal{C}) \setminus LE(\mathcal{C}))$.

5 An example is given in Figure 5. We denote by $\text{Top}(\mathcal{C})$ the set of top squares of
6 \mathcal{C} . Note that a square may satisfy more than one of the conditions above; indeed,
7 there is no square set $\mathcal{C} \subseteq \mathcal{D}_i$ such that $|\text{Top}(\mathcal{C})| = 16$ since the rightmost square
8 in \mathcal{C} always satisfies both (i) and (ii).

9 A square set $\mathcal{F} \subseteq \mathcal{D}_i$ is *feasible on \mathcal{D}_i* if $\text{Top}(\mathcal{F}) = \mathcal{F}$. For a feasible square
10 set $\mathcal{F} \subseteq \mathcal{D}_i$, we denote by $\mathfrak{C}_i(\mathcal{F})$ the set of all square subsets of \mathcal{D}_i whose top
11 squares are equal to \mathcal{F} , that is,

$$\mathfrak{C}_i(\mathcal{F}) = \{\mathcal{C} \subseteq \mathcal{D}_i \mid \text{Top}(\mathcal{C}) = \mathcal{F}\}.$$

12 A top square S in a feasible set \mathcal{F} is said to be *stable in \mathcal{F}* if $\Delta(\mathcal{C}, S)$ consists
13 only of top squares in \mathcal{F} for any square set $\mathcal{C} \in \mathfrak{C}_i(\mathcal{F})$. The following lemma
14 implies that, for a feasible square set $\mathcal{F} \subseteq \mathcal{D}_i$, we can check in polynomial time
15 whether a top square $S \in \mathcal{F}$ is stable in \mathcal{F} .

16 **Lemma 3.2.** *Let S be any (top) square in a feasible set $\mathcal{F} \subseteq \mathcal{D}_i$. Then, S is*
17 *stable in \mathcal{F} if and only if $S' \notin \Delta(\mathcal{F} \cup \{S'\}, S)$ holds for every square $S' \in \mathcal{D}_i \setminus \mathcal{F}$*
18 *such that $\text{Top}(\mathcal{F} \cup \{S'\}) = \mathcal{F}$.*

19 **PROOF.** By the definition of stable squares, the necessity clearly holds. We thus
20 show the sufficiency: If S is not stable in \mathcal{F} , then there exists a non-top square
21 $S' \in \mathcal{D}_i \setminus \mathcal{F}$ such that $\text{Top}(\mathcal{F} \cup \{S'\}) = \mathcal{F}$ and $S' \in \Delta(\mathcal{F} \cup \{S'\}, S)$.

1 Since S is not stable in \mathcal{F} , there exists a square set $\mathcal{C} \in \mathfrak{C}_i(\mathcal{F})$ such that
 2 $\Delta(\mathcal{C}, S)$ contains non-top squares of \mathcal{C} . Let S' be an arbitrary non-top square
 3 in $\mathcal{C} \setminus \mathcal{F}$. Then, we have $\text{Top}(\mathcal{F} \cup \{S'\}) = \mathcal{F}$ and $S' \in \Delta(\mathcal{F} \cup \{S'\}, S)$. \square

4 Indeed, stable top squares will be crucial to our algorithm: If a top square S
 5 is stable in a feasible set $\mathcal{F} \subseteq \mathcal{D}_i$, then $\Delta(\mathcal{C}, S)$ contains at most 16 top squares
 6 in \mathcal{F} for any square set $\mathcal{C} \in \mathfrak{C}_i(\mathcal{F})$; and hence we can compute $\Delta(\mathcal{C}, S)$ in poly-
 7 nomial time. Therefore, below is the key lemma for our dynamic programming
 8 algorithm, whose proof will be given in Section 4.1.

9 **Lemma 3.3.** *For any feasible square set $\mathcal{F} \subseteq \mathcal{D}_i$, there always exists a top*
 10 *square $K(\mathcal{F})$ which is stable in \mathcal{F} . Moreover, $K(\mathcal{F})$ can be found in polynomial*
 11 *time.*

12 The proof of Lemma 3.3 is postponed to Section 4.1. In most cases, we
 13 choose the rightmost square of \mathcal{F} as $K(\mathcal{F})$. However, when the rightmost square
 14 intersects too many other squares, such a choice does not work. Indeed, $K(\mathcal{F})$
 15 will be one of the following five squares:

- 16 1. the rightmost square of \mathcal{F} ;
- 17 2. the rightmost square of $LE(\mathcal{F}) \setminus UE(\mathcal{F})$;
- 18 3. the second rightmost square of $LE(\mathcal{F}) \setminus UE(\mathcal{F})$;
- 19 4. the rightmost square of $UE(\mathcal{F}) \setminus LE(\mathcal{F})$; and
- 20 5. the second rightmost square of $UE(\mathcal{F}) \setminus LE(\mathcal{F})$.

21 In Figure 5, $K(\mathcal{F})$ is the rightmost square. In Figure 6, the left figure shows a
 22 case where $K(\mathcal{F})$ is the rightmost square of $LE(\mathcal{F}) \setminus UE(\mathcal{F})$ and the right figure
 23 shows a case where $K(\mathcal{F})$ is the second rightmost square of $LE(\mathcal{F}) \setminus UE(\mathcal{F})$.
 24 The other two cases can be obtained symmetrically.

25 3.4. Algorithm for the problem on $\langle \mathcal{P} \cap (R_{i-1} \cup R_i), \mathcal{D}_i \rangle$

26 To gain intuition, we first present the dynamic programming algorithm when
 27 the set of points is restricted to $\mathcal{P} \cap (R_{i-1} \cup R_i)$ and the set of squares is restricted
 28 to \mathcal{D}_i . **We later generalize this approach to the general case.** Let $G = R_{i-1} \cup R_i$.
 29 We want to solve the problem on $\langle \mathcal{P} \cap G, \mathcal{D}_i \rangle$ optimally in polynomial time.

30 For a feasible square set \mathcal{F} on \mathcal{D}_i , let $f(\mathcal{F})$ be the maximum number of
 31 points in $\mathcal{P} \cap G$ uniquely covered by a square set in $\mathfrak{C}_i(\mathcal{F})$, that is,

$$f(\mathcal{F}) = \max\{\text{profit}(\mathcal{P} \cap G, \mathcal{C}) \mid \mathcal{C} \in \mathfrak{C}_i(\mathcal{F})\},$$

32 where $\text{profit}(\mathcal{P} \cap G, \mathcal{C})$ is the number of points in $\mathcal{P} \cap G$ that are uniquely covered
 33 by \mathcal{C} . Then, since every subset of \mathcal{D}_i belongs to $\mathfrak{C}_i(\mathcal{F})$ for some feasible set \mathcal{F} ,
 34 the optimal value $\text{OPT}(\mathcal{P} \cap G, \mathcal{D}_i)$ for $\langle \mathcal{P} \cap G, \mathcal{D}_i \rangle$ can be computed as

$$\text{OPT}(\mathcal{P} \cap G, \mathcal{D}_i) = \max\{f(\mathcal{F}) \mid \mathcal{F} \text{ is feasible on } \mathcal{D}_i\}.$$

35 Since $|\mathcal{F}| < 16$, this computation can be done in polynomial time if we have the
 36 values $f(\mathcal{F})$ for all feasible square sets \mathcal{F} on \mathcal{D}_i .

Figure 6: The choice of stable squares. The blue squares are top squares, and the red one is stable. (Left) The rightmost square of $LE(\mathcal{F}) \setminus UE(\mathcal{F})$ is stable in \mathcal{F} . (Right) The second rightmost square of $LE(\mathcal{F}) \setminus UE(\mathcal{F})$ is stable in \mathcal{F} . In each of the figures, the gray region depicts $A_1(\mathcal{C} \setminus \{S\}) \setminus A_1(\mathcal{C})$ when S is the red square. We may observe that $\Delta(\mathcal{C}, S)$ consists only of top squares. On the other hand, $\Delta(\mathcal{C}, S)$ contains a non-top square (black square) when S is the rightmost square (a thick blue square). **Note that, in the right figure, the rightmost square of $LE(\mathcal{F}) \setminus UE(\mathcal{F})$ is not stable in \mathcal{F} , and neither of the rightmost square nor the second rightmost square of $UE(\mathcal{F}) \setminus LE(\mathcal{F})$ is stable in \mathcal{F} .**

1 We thus compute $f(\mathcal{F})$ in polynomial time for all feasible square sets \mathcal{F} on
2 \mathcal{D}_i , according to the “parent-child relation.” For two feasible square sets \mathcal{F} and
3 \mathcal{F}' on \mathcal{D}_i , we say that \mathcal{F}' is a *child* of \mathcal{F} if there exists a square set $\mathcal{C} \in \mathfrak{C}_i(\mathcal{F})$
4 such that $\text{Top}(\mathcal{C} \setminus \{K(\mathcal{F})\}) = \mathcal{F}'$. **The parent-child relation for the feasible**
5 **square sets on \mathcal{D}_i is a binary relation specified by “ \mathcal{F} is a child of \mathcal{F}' ,” which**
6 **may also be viewed as a directed graph such that the vertex set is the family of**
7 **feasible square sets on \mathcal{D}_i and an arc exists from \mathcal{F}' to \mathcal{F} if and only if \mathcal{F} is a**
8 **child of \mathcal{F}' .**

9 **Lemma 3.4.** *The parent-child relation for the feasible square sets on \mathcal{D}_i can*
10 *be constructed in polynomial time. Furthermore, the parent-child relation is*
11 *acyclic.*

12 **PROOF.** We can enumerate all feasible square sets on \mathcal{D}_i as follows: We first
13 generate all sets $\mathcal{C} \subseteq \mathcal{D}_i$ consisting of 16 squares, and then check whether
14 $\text{Top}(\mathcal{C}) = \mathcal{C}$. The number of candidates for \mathcal{C} is bounded by $|\mathcal{D}_i|^{16}$ and the
15 check can be done in polynomial time. Therefore, the enumeration can be per-
16 formed in polynomial time.

17 For a feasible square set \mathcal{F} on \mathcal{D}_i , let \mathcal{C} be any square set in $\mathfrak{C}_i(\mathcal{F})$. Then, we
18 have $|\text{Top}(\mathcal{C} \setminus \{K(\mathcal{F})\}) \setminus \text{Top}(\mathcal{C})| \leq 2$ since the top square $K(\mathcal{F})$ can appear in
19 at most two sets among $UE(\mathcal{C})$, $LE(\mathcal{C})$, $UE(LE(\mathcal{C}) \setminus UE(\mathcal{C}))$ and $LE(UE(\mathcal{C}) \setminus$
20 $LE(\mathcal{C}))$. Therefore, the number of candidates of children of \mathcal{F} can be bounded
21 by $O(|\mathcal{D}_i|^2)$. We can thus construct the parent-child relation in polynomial
22 time.

23 For acyclicity, consider the sequence of the x -coordinates of top squares
24 from right to left. Any child \mathcal{F}' has a sequence lexicographically smaller than

1 its parent \mathcal{F} , or $\mathcal{F}' \subset \mathcal{F}$. This implies that the parent-child relation is acyclic.
 2 \square

3 With the parent-child relation, we give the algorithm that solves the problem
 4 on $\langle \mathcal{P} \cap G, \mathcal{D}_i \rangle$.

5 Let \mathcal{D}^0 be the square set consisting of the leftmost 16 squares in \mathcal{D}_i . As the
 6 initialization, we first compute $f(\mathcal{F})$ for all feasible sets \mathcal{F} on \mathcal{D}^0 . Since $|\mathcal{D}^0|$ is
 7 constant, the total number of feasible sets \mathcal{F} on \mathcal{D}^0 is also constant. Therefore,
 8 this initialization can be done in polynomial time.

9 We then compute $f(\mathcal{F})$ for a feasible square set \mathcal{F} on \mathcal{D}_i from the values
 10 $f(\mathcal{F}')$ for all children \mathcal{F}' of \mathcal{F} . Since the parent-child relation is acyclic, we can
 11 find a feasible square set \mathcal{F} such that the values $f(\mathcal{F}')$ are already computed
 12 for all children \mathcal{F}' of \mathcal{F} . For a square set $\mathcal{C} \subseteq \mathcal{D}_i$ and a square $S \in \mathcal{C}$, we
 13 denote by $z(\mathcal{C}, S)$ the difference of the number of uniquely covered points in
 14 $\mathcal{P} \cap G$ caused by adding S to $\mathcal{C} \setminus \{S\}$, that is, the number of points in $\mathcal{P} \cap G$
 15 that are included in $S \cap A_1(\mathcal{C})$ minus the number of points in $\mathcal{P} \cap G$ that are
 16 included in $S \cap A_1(\mathcal{C} \setminus \{S\})$. By the definition of a stable square, we have
 17 $z(\mathcal{F}, K(\mathcal{F})) = z(\mathcal{C}, K(\mathcal{F}))$ for all square sets $\mathcal{C} \in \mathfrak{C}_i(\mathcal{F})$. Therefore, we can
 18 correctly compute $f(\mathcal{F})$ by

$$f(\mathcal{F}) = \max\{f(\mathcal{F}') \mid \mathcal{F}' \text{ is a child of } \mathcal{F}\} + z(\mathcal{F}, K(\mathcal{F})).$$

19 This way, the algorithm correctly solves the problem on $\langle \mathcal{P} \cap G, \mathcal{D}_i \rangle$ in polynomial
 20 time.

21 3.5. Properties on square subsets of \mathcal{D}

22 We then get back to the general case where we want to solve the problem
 23 on $\langle \mathcal{P} \cap G, \mathcal{D} \rangle$. Remember that the ribbons R_0, R_1, \dots, R_{k+1} are ordered from
 24 bottom to top, and that \mathcal{D}_i is the set of all squares in \mathcal{D} intersecting the lower
 25 boundary of R_i for each $i \in \{1, \dots, k+1\}$. For a square set $\mathcal{C} \subseteq \mathcal{D}$, let $\mathcal{C}_i = \mathcal{C} \cap \mathcal{D}_i$
 26 for each $i \in \{1, \dots, k+1\}$. Then, these square sets $\mathcal{C}_1, \mathcal{C}_2, \dots, \mathcal{C}_{k+1}$ form a
 27 partition of \mathcal{C} .

28 The plan is as follows.

- 29 • We look at the parts $\mathcal{C}_1, \mathcal{C}_2, \dots, \mathcal{C}_{k+1}$ in the partition of \mathcal{C} , and consider
 30 a set of top squares in each part. This way, we may obtain the union of
 31 $k+1$ sets of top squares.
- 32 • We prove in Lemma 3.5 that there exists at least one top square S in this
 33 union such that $\Delta(\mathcal{C}, S)$ consists only of top squares in this union. This
 34 square S can be treated as a “stable” square in this general case.
- 35 • The property above enables us to develop a dynamic-programming algo-
 36 rithm as hinted in Section 3.4.

37 We will follow this plan, and introduce the relevant concepts.

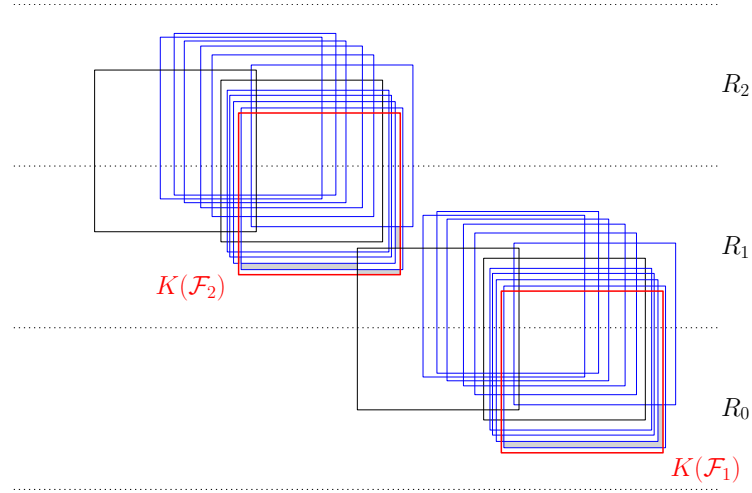

Figure 7: An illustration of a safe family. The blue squares form \mathcal{F} , and $K(\mathcal{F}_1)$ and $K(\mathcal{F}_2)$ are shown as red squares. Since $\Delta(\mathcal{C}, K(\mathcal{F}_2))$ has one square that does not belong to \mathcal{F} , \mathcal{F}_2 is not safe for \mathcal{F} . On the other hand, \mathcal{F}_1 is safe for \mathcal{F} as $\Delta(\mathcal{C}, K(\mathcal{F}_1)) \subset \mathcal{F}$. The gray region shows $A_1(\mathcal{C} \setminus \{S\}) \setminus A_1(\mathcal{C})$ when S is one of the red squares.

1 A square set $\mathcal{F} \subseteq \mathcal{D}$ is *feasible on \mathcal{D}* if $\text{Top}(\mathcal{F} \cap \mathcal{D}_i) = \mathcal{F} \cap \mathcal{D}_i$ for each
2 $i \in \{1, \dots, k+1\}$. For a feasible square set \mathcal{F} on \mathcal{D} and $i \in \{1, \dots, k+1\}$, we
3 denote by $\mathcal{F}_i = \mathcal{F} \cap \mathcal{D}_i$, and let

$$\mathfrak{C}(\mathcal{F}) = \{\mathcal{C} \subseteq \mathcal{D} \mid \text{Top}(\mathcal{C}_i) = \mathcal{F}_i \text{ for each } i \in \{1, \dots, k+1\}\}.$$

4 We say that \mathcal{F}_i is *safe for \mathcal{F}* if $\Delta(\mathcal{C}, K(\mathcal{F}_i)) \subset \mathcal{F}$ for any square set $\mathcal{C} \in \mathfrak{C}(\mathcal{F})$,
5 where $K(\mathcal{F}_i)$ is the stable top square in \mathcal{F}_i which is selected as in the proof of
6 Lemma 3.3. In Figure 7, a case where $k = 2$ is illustrated. There, \mathcal{F}_1 is safe for
7 \mathcal{F} , but \mathcal{F}_2 is not safe for \mathcal{F} .

8 The below is another key lemma for our dynamic programming algorithm,
9 which shows at least one \mathcal{F}_q is safe for \mathcal{F} .

10 **Lemma 3.5.** *For any feasible square set \mathcal{F} on \mathcal{D} , there exists an index $q \in$
11 $\{1, \dots, k+1\}$ such that \mathcal{F}_q is safe for \mathcal{F} .*

12 The proof will be given in Section 4.2.

13 3.6. Algorithm for the problem on $\langle \mathcal{P} \cap G, \mathcal{D} \rangle$

14 We are now ready to describe our algorithm for the problem on $\langle \mathcal{P} \cap G, \mathcal{D} \rangle$.
15 The algorithm follows the guidance of Section 3.4, but the treatment is much
16 more general here.

17 For a feasible square set \mathcal{F} on \mathcal{D} , let $f(\mathcal{F})$ be the maximum number of points
18 in $\mathcal{P} \cap G$ uniquely covered by a square set in $\mathfrak{C}(\mathcal{F})$, that is,

$$f(\mathcal{F}) = \max\{\text{profit}(\mathcal{P} \cap G, \mathcal{C}) \mid \mathcal{C} \in \mathfrak{C}(\mathcal{F})\},$$

1 where $\text{profit}(\mathcal{P} \cap G, \mathcal{C})$ is the number of points in $\mathcal{P} \cap G$ that are uniquely covered
 2 by \mathcal{C} . Then, since every subset of \mathcal{D} belongs to $\mathfrak{C}(\mathcal{F})$ for some feasible set \mathcal{F} ,
 3 the optimal value $\text{OPT}(\mathcal{P} \cap G, \mathcal{D})$ for $\langle \mathcal{P} \cap G, \mathcal{D} \rangle$ can be computed as

$$\text{OPT}(\mathcal{P} \cap G, \mathcal{D}) = \max\{f(\mathcal{F}) \mid \mathcal{F} \text{ is feasible on } \mathcal{D}\}.$$

4 Since $|\mathcal{F}| < 16(k+1)$, this computation can be done in polynomial time if we
 5 have the values $f(\mathcal{F})$ for all feasible square sets \mathcal{F} on \mathcal{D} .

6 We thus compute $f(\mathcal{F})$ in polynomial time for all feasible square sets \mathcal{F} on
 7 \mathcal{D} , according to the “parent-child relation.” For a square set $\mathcal{C} \subseteq \mathcal{D}$, we denote
 8 simply by $\text{Top}(\mathcal{C}) = \bigcup_{1 \leq i \leq k+1} \text{Top}(\mathcal{C}_i)$. For a feasible square set \mathcal{F} on \mathcal{D} , let
 9 $K(\mathcal{F}) = K(\mathcal{F}_q)$ where $\mathcal{F}_q = \mathcal{F} \cap \mathcal{D}_q$ is safe for \mathcal{F} . For two feasible square
 10 sets \mathcal{F} and \mathcal{F}' on \mathcal{D} , we say that \mathcal{F}' is a *child* of \mathcal{F} if there exists a square set
 11 $\mathcal{C} \in \mathfrak{C}(\mathcal{F})$ such that $\text{Top}(\mathcal{C} \setminus \{K(\mathcal{F})\}) = \mathcal{F}'$. **The parent-child relation for the
 12 feasible square sets on \mathcal{D} is a binary relation specified by “ \mathcal{F} is a child of \mathcal{F}' ,”
 13 which may also be viewed as a directed graph as before.**

14 **Lemma 3.6.** *The parent-child relation for the feasible square sets on \mathcal{D} can
 15 be constructed in polynomial time. Furthermore, the parent-child relation is
 16 acyclic.*

17 **PROOF.** We can enumerate all feasible square sets on \mathcal{D} , as follows: We first
 18 generate all sets $\mathcal{C} \subseteq \mathcal{D}$ consisting of $16(k+1)$ squares, and then check whether
 19 $\text{Top}(\mathcal{C} \cap \mathcal{D}_i) = \mathcal{C} \cap \mathcal{D}_i$ for each $i \in \{1, \dots, k+1\}$. Since k is a constant, this
 20 enumeration can be done in polynomial time.

21 For a feasible square set \mathcal{F} on \mathcal{D} , let \mathcal{C} be any square set in $\mathfrak{C}(\mathcal{F})$. Then,
 22 we have $|\text{Top}(\mathcal{C} \setminus \{K(\mathcal{F})\}) \setminus \text{Top}(\mathcal{C})| \leq 2$ since the top square $K(\mathcal{F}) = K(\mathcal{F}_q)$
 23 can appear in at most two sets among $UE(\mathcal{C}_q)$, $LE(\mathcal{C}_q)$, $UE(LE(\mathcal{C}_q) \setminus UE(\mathcal{C}_q))$
 24 and $LE(UE(\mathcal{C}_q) \setminus LE(\mathcal{C}_q))$. Therefore, the number of candidates of children of
 25 \mathcal{F} can be bounded by $O(|\mathcal{D}|^2)$. We can thus construct the parent-child relation
 26 in polynomial time.

27 Consider the sequence of the x -coordinates of top squares from right to left.
 28 Any child \mathcal{F}' has a sequence lexicographically smaller than its parent \mathcal{F} , or
 29 $\mathcal{F}' \subset \mathcal{F}$. This implies that the parent-child relation is acyclic. \square

30 We finally give the algorithm that solves the problem on $\langle \mathcal{P} \cap G, \mathcal{D} \rangle$.

31 For each $i \in \{1, \dots, k+1\}$, let \mathcal{D}_i^0 be the square set consisting of the first 16
 32 squares in \mathcal{D}_i having the smallest x -coordinates. Let $\mathcal{D}^0 = \bigcup_{1 \leq i \leq k+1} \mathcal{D}_i^0$, then
 33 $|\mathcal{D}^0| \leq 16(k+1)$. As the initialization, we first compute $f(\mathcal{F})$ for all feasible
 34 sets \mathcal{F} on \mathcal{D}^0 . Since $|\mathcal{D}^0|$ is a constant, the total number of feasible sets \mathcal{F} on
 35 \mathcal{D}^0 is also a constant. Therefore, this initialization can be done in polynomial
 36 time.

37 We then compute $f(\mathcal{F})$ for a feasible square set \mathcal{F} on \mathcal{D} from the values
 38 $f(\mathcal{F}')$ for all children \mathcal{F}' of \mathcal{F} . Since the parent-child relation is acyclic, we can
 39 find a feasible square set \mathcal{F} such that the values $f(\mathcal{F}')$ are already computed
 40 for all children \mathcal{F}' of \mathcal{F} . By Lemma 3.5 there always exists a feasible square
 41 set $\mathcal{F}_q = \mathcal{F} \cap \mathcal{D}_q$ on \mathcal{D}_q which is safe for \mathcal{F} , and hence by Lemma 3.3 we

1 have a stable top square $K(\mathcal{F}) = K(\mathcal{F}_q)$ in polynomial time. For a square set
2 $\mathcal{C} \subseteq \mathcal{D}$ and a square $S \in \mathcal{C}$, we denote by $z(\mathcal{C}, S)$ the difference of the number
3 of uniquely covered points in $\mathcal{P} \cap G$ caused by adding S to $\mathcal{C} \setminus \{S\}$, that is, the
4 number of points in $\mathcal{P} \cap G$ that are included in $S \cap A_1(\mathcal{C})$ minus the number
5 of points in $\mathcal{P} \cap G$ that are included in $S \cap A_1(\mathcal{C} \setminus \{S\})$. Since \mathcal{F}_q is safe for
6 \mathcal{F} and $K(\mathcal{F}) = K(\mathcal{F}_q)$, we have $z(\mathcal{F}, K(\mathcal{F})) = z(\mathcal{C}, K(\mathcal{F}))$ for all square sets
7 $\mathcal{C} \in \mathfrak{C}(\mathcal{F})$. Therefore, we can correctly update $f(\mathcal{F})$ by

$$f(\mathcal{F}) := \max\{f(\mathcal{F}') \mid \mathcal{F}' \text{ is a child of } \mathcal{F}\} + z(\mathcal{F}, K(\mathcal{F})). \quad (2)$$

8 This way, the algorithm correctly solves the problem on $\langle \mathcal{P} \cap G, \mathcal{D} \rangle$ in polynomial
9 time.

10 This completes the proof of Lemma 3.1. \square

11 4. Proofs of key lemmas

12 To finalize the whole proof, we give proofs of Lemmas 3.3 and 3.5 in Sections
13 4.1 and 4.2, respectively.

14 4.1. Proof of Lemma 3.3

15 To prove Lemma 3.3, we need a thorough preparation. We first give several
16 properties on squares composing uniquely covered regions. Using them, we then
17 give the proof of Lemma 3.3. Remember that we deal with squares only in a
18 set $\mathcal{C} \subseteq \mathcal{D}_i$ and the region uniquely covered by them.

19 4.1.1. Upper and lower envelopes

20 We first give the following lemma for the upper envelope; its counterpart
21 holds for the lower envelope by a symmetric argument.

22 **Lemma 4.1.** *Let $\mathcal{C} \subseteq \mathcal{D}_i$ be a square set, and suppose that a square $S \in \mathcal{C}$ is
23 not in $UE(\mathcal{C})$. Then, any point in $S \cap R_i$ is covered by at least one square in
24 $UE(\mathcal{C})$.*

25 We remind that $x(S)$ and $y(S)$ refer to the coordinates of the top right corner
26 of S .

27 **PROOF.** Let $p = (x, y) \in S \cap R_i$ be an arbitrary point. Consider the vertical
28 line ℓ through p . Then, ℓ meets the upper envelope in R_i . Let $S' \in UE(\mathcal{C})$ be
29 a square that meets ℓ . Since $S \notin UE(\mathcal{C})$, it holds that $x(S') - 1 < x < x(S')$
30 and $y \leq y(S) < y(S')$. Since $p \in R_i$ and $S' \in \mathcal{C} \subseteq \mathcal{D}_i$, we have $y(S') - 1 < y$.
31 Therefore, $p \in S'$. \square

32 We give the following lemma for the upper envelope.

33 **Lemma 4.2.** *Let S and S' be any two squares in a square set $\mathcal{C} \subseteq \mathcal{D}_i$ with
34 $x(S) < x(S')$. Suppose that there are q squares S_1, S_2, \dots, S_q , $q \geq 1$, such that
35 $S_j \in UE(\mathcal{C})$ and $x(S) < x(S_j) < x(S')$ for each index $j \in \{1, \dots, q\}$. Then, any
36 point in $S \cap S' \cap R_i$ is covered by at least $2 + q$ squares unless the intersection
37 is empty.*

1 PROOF. We show that every point $p' = (x', y')$ in $S \cap S' \cap R_i$ is covered by every
 2 square S_j , $1 \leq j \leq q$, that is, both $x(S_j) - 1 \leq x' \leq x(S_j)$ and $y(S_j) - 1 \leq y' \leq$
 3 $y(S_j)$ hold.

4 We first show that $x(S_j) - 1 \leq x' \leq x(S_j)$ holds. Since $p' \in S \cap S' \cap R_i$ and
 5 $x(S) < x(S')$, we have $x(S') - 1 \leq x' \leq x(S)$. Then, since $x(S) < x(S_j) < x(S')$,
 6 we have $x(S_j) - 1 < x(S') - 1 \leq x' \leq x(S) < x(S_j)$.

7 We then show that $y(S_j) - 1 \leq y' \leq y(S_j)$ holds. Since all the squares in
 8 \mathcal{D}_i intersect the lower boundary of R_i , we have $y(S_j) - 1 \leq y'$. On the other
 9 hand, suppose for a contradiction that $y' > y(S_j)$ holds. Since $p' \in S \cap S' \cap R_i$,
 10 we have $y' \leq \min\{y(S), y(S')\}$. Then, we have $y(S_j) < y' \leq \min\{y(S), y(S')\}$.
 11 Since $x(S) < x(S_j) < x(S')$, every point $(x'', y(S_j))$, composing the top side of
 12 S_j , is contained in $S \cup S'$, where $x(S) - 1 < x(S_j) - 1 \leq x'' \leq x(S_j) < x(S')$.
 13 Thus, the top side of S_j does not appear in the upper envelope of \mathcal{C} at all. This
 14 contradicts $S_j \in UE(\mathcal{C})$. \square

15 Similar arguments establish the counterpart for the lower envelope, as fol-
 16 lows.

17 **Lemma 4.3.** *Let S and S' be any two squares in a square set $\mathcal{C} \subseteq \mathcal{D}_i$ with*
 18 *$x(S) < x(S')$. Suppose that there are q squares S_1, S_2, \dots, S_q , $q \geq 1$, such that*
 19 *$S_j \in LE(\mathcal{C})$ and $x(S) < x(S_j) < x(S')$ for each index $j \in \{1, \dots, q\}$. Then, any*
 20 *point in $S \cap S' \cap R_{i-1}$ is covered by at least $2 + q$ squares unless the intersection*
 21 *is empty.*

22 4.1.2. Top squares

23 We denote by $U\Delta(\mathcal{C}, S)$ the set of all squares that form the boundary of
 24 $(A_1(\mathcal{C} \setminus \{S\}) \setminus A_1(\mathcal{C})) \cap R_i$, and by $L\Delta(\mathcal{C}, S)$ the set of all squares that form the
 25 boundary of $(A_1(\mathcal{C} \setminus \{S\}) \setminus A_1(\mathcal{C})) \cap R_{i-1}$. By the definition, we clearly have
 26 the following lemma.

27 **Lemma 4.4.** *Let S and S' be two squares in a set $\mathcal{C} \subseteq \mathcal{D}_i$. Then, S' is not in*
 28 *$U\Delta(\mathcal{C}, S)$ if any point in $S' \cap S \cap R_i$ is contained in $A_{\geq 3}(\mathcal{C} \setminus \{S\})$. Similarly, S'*
 29 *is not in $L\Delta(\mathcal{C}, S)$ if any point in $S' \cap S \cap R_{i-1}$ is contained in $A_{\geq 3}(\mathcal{C} \setminus \{S\})$.*
 30 \square

31 For a feasible square set $\mathcal{F} \subseteq \mathcal{D}_i$, let $UE(\mathcal{F}) = (K_1^\top, K_2^\top, \dots, K_\alpha^\top)$ with

$$x(K_\alpha^\top) < x(K_{\alpha-1}^\top) < \dots < x(K_1^\top), \quad (3)$$

32 and let $LE(\mathcal{F}) = (K_1^\perp, K_2^\perp, \dots, K_\beta^\perp)$ with

$$x(K_\beta^\perp) < x(K_{\beta-1}^\perp) < \dots < x(K_1^\perp). \quad (4)$$

33 Note that some squares may appear in both $UE(\mathcal{F})$ and $LE(\mathcal{F})$. In particular,
 34 we always have $K_1^\top = K_1^\perp$. Then, we have the following lemma.

35 **Lemma 4.5.** *For a square $K_j^\top \in UE(\mathcal{F})$, $1 \leq j \leq 4$, suppose that there exists*
 36 *a square set $\mathcal{C} \in \mathfrak{C}_i(\mathcal{F})$ such that $U\Delta(\mathcal{C}, K_j^\top)$ contains a non-top square Q of*
 37 *\mathcal{C} with $x(Q) < x(K_j^\top)$. Then, $|LE(\mathcal{F})| \geq 6$ and either $|UE(\mathcal{F})| \leq j + 1$ or*
 38 *$x(K_{j+2}^\top) < x(K_6^\perp)$ holds.*

1 PROOF. We first claim that there exists at most one square $K^\top \in UE(\mathcal{C})$
2 such that $x(Q) < x(K^\top) < x(K_j^\top)$. Suppose for a contradiction that there
3 exist two squares $K, K' \in UE(\mathcal{C})$ such that $x(Q) < x(K) < x(K') < x(K_j^\top)$.
4 Then, by Lemma 4.2 every point in $Q \cap K_j^\top \cap R_i$ is covered by at least four
5 squares and hence is contained in $A_{\geq 3}(\mathcal{C} \setminus \{K_j^\top\})$. By Lemma 4.4 we then have
6 $Q \notin U\Delta(\mathcal{C}, K_j^\top)$, a contradiction.

7 This claim implies that $Q \notin UE(\mathcal{C})$; otherwise, since $1 \leq j \leq 4$, we have
8 $Q \in \{K_2^\top, K_3^\top, K_4^\top, K_5^\top, K_6^\top\}$ and hence Q is a top square in \mathcal{F} . Remember that
9 each square in \mathcal{C} appears in $UE(\mathcal{C})$ or $LE(\mathcal{C})$, and hence we have $Q \in LE(\mathcal{C})$.
10 Then, since $\text{Top}(\mathcal{C}) = \mathcal{F}$ and $Q \notin \mathcal{F}$, we have $|LE(\mathcal{F})| \geq 6$ and

$$x(Q) < x(K_6^\perp). \quad (5)$$

11 The claim also implies that either $|UE(\mathcal{F})| \leq j + 1$ or

$$x(K_{j+2}^\top) < x(Q) \quad (6)$$

12 holds. By Eqs. (5) and (6) we have $x(K_{j+2}^\top) < x(K_6^\perp)$, as required. \square

13 Similar arguments establish the counterpart of Lemma 4.5, as follows.

14 **Lemma 4.6.** *For a square $K_j^\perp \in LE(\mathcal{F})$, $1 \leq j \leq 4$, suppose that there exists*
15 *a square set $\mathcal{C} \in \mathfrak{C}_i(\mathcal{F})$ such that $L\Delta(\mathcal{C}, K_j^\perp)$ contains a non-top square Q of*
16 *\mathcal{C} with $x(Q) < x(K_j^\perp)$. Then, $|UE(\mathcal{F})| \geq 6$ and either $|LE(\mathcal{F})| \leq j + 1$ or*
17 *$x(K_{j+2}^\perp) < x(K_6^\top)$ holds. \square*

18 Using Lemmas 4.5 and 4.6, we have the following lemma.

19 **Lemma 4.7.** *For a feasible square set $\mathcal{F} \subseteq \mathcal{D}_i$, let S_1 be the square in \mathcal{F} with*
20 *the largest x -coordinate. Then, the following (a) and (b) hold:*

- 21 (a) *If there exists a square set $\mathcal{C} \in \mathfrak{C}_i(\mathcal{F})$ such that $U\Delta(\mathcal{C}, S_1)$ contains*
22 *a non-top square of \mathcal{C} , then $L\Delta(\mathcal{C}', S_1) \subset \mathcal{F}$ holds for all square sets*
23 *$\mathcal{C}' \in \mathfrak{C}_i(\mathcal{F})$;*
24 (b) *If there exists a square set $\mathcal{C} \in \mathfrak{C}_i(\mathcal{F})$ such that $L\Delta(\mathcal{C}, S_1)$ contains*
25 *a non-top square of \mathcal{C} , then $U\Delta(\mathcal{C}', S_1) \subset \mathcal{F}$ holds for all square sets*
26 *$\mathcal{C}' \in \mathfrak{C}_i(\mathcal{F})$.*

27 The situation (a) is illustrated in Figure 6 (left).

28 PROOF. Note that $S_1 = K_1^\top = K_1^\perp$. We show that (a) holds. (The proof for
29 (b) is similar.)

30 Suppose that there exists a square set $\mathcal{C} \in \mathfrak{C}_i(\mathcal{F})$ such that $U\Delta(\mathcal{C}, S_1)$ con-
31 tains a non-top square Q of \mathcal{C} . Since S_1 is the square with the largest x -
32 coordinate, we have $x(Q) < x(S_1)$. Then, since $S_1 = K_1^\top$, by Lemma 4.5 we
33 have

$$|LE(\mathcal{F})| \geq 6 \quad (7)$$

34 and either $|UE(\mathcal{F})| \leq 2$ or

$$x(K_3^\top) < x(K_6^\perp) \quad (8)$$

1 holds.

2 We now show that $L\Delta(\mathcal{C}', S_1) \subset \mathcal{F}$ holds for all square sets $\mathcal{C}' \in \mathfrak{C}_i(\mathcal{F})$.
 3 Suppose for a contradiction that there exists a square set $\mathcal{C}'' \in \mathfrak{C}_i(\mathcal{F})$ such that
 4 $L\Delta(\mathcal{C}'', S_1)$ contains a non-top square Q' of \mathcal{C}'' . Then, since $S_1 = K_1^\perp$ and
 5 $x(Q') < x(S_1)$, by Lemma 4.6 we have $|UE(\mathcal{F})| \geq 6$ and either $|LE(\mathcal{F})| \leq 2$ or
 6 $x(K_3^\perp) < x(K_6^\top)$ holds. By Eq. (7) we thus have

$$x(K_3^\perp) < x(K_6^\top). \quad (9)$$

7 Moreover, the inequality $|UE(\mathcal{F})| \geq 6$ implies that Eq. (8) holds. Therefore, by
 8 Eqs. (4), (8) and (9) we have $x(K_3^\top) < x(K_6^\top)$. This contradicts Eq. (3). \square

9 Note that Lemma 4.7 implies that, for any square set $\mathcal{C} \in \mathfrak{C}_i(\mathcal{F})$, at most
 10 one of $U\Delta(\mathcal{C}, S_1)$ and $L\Delta(\mathcal{C}, S_1)$ can contain non-top squares of \mathcal{C} .

11 4.1.3. Proof of Lemma 3.3

12 We now prove Lemma 3.3. We consider the following cases, and prove that
 13 there is a stable top square $K(\mathcal{F})$ in each case. Let S_1 be the square in \mathcal{F} whose
 14 x -coordinate is largest. Note that $S_1 = K_1^\top = K_1^\perp$.

15 **Case 1:** S_1 is stable in \mathcal{F} .

16 In this case, we set $K(\mathcal{F}) = S_1$. Note that by Lemma 3.2 we can check
 17 whether S_1 is stable in \mathcal{F} in polynomial time.

18 **Case 2:** S_1 is not stable in \mathcal{F} .

19 Since S_1 is not stable in \mathcal{F} , by Lemma 3.2 there exists a non-top square
 20 $Q \in \mathcal{D}_i \setminus \mathcal{F}$ such that $Q \in \Delta(\mathcal{F} \cup \{Q\}, S_1)$ and $\text{Top}(\mathcal{F} \cup \{Q\}) = \mathcal{F}$. Lemma 4.7
 21 allows us to assume $Q \in U\Delta(\mathcal{F} \cup \{Q\}, S_1)$ without loss of generality. (The case
 22 for $Q \in L\Delta(\mathcal{F} \cup \{Q\}, S_1)$ is symmetric.) Then, by Lemma 4.5 we have

$$|LE(\mathcal{F})| \geq 6 \quad (10)$$

23 and either $|UE(\mathcal{F})| \leq 2$ or

$$x(K_3^\top) < x(K_6^\perp) \quad (11)$$

24 holds.

25 Consider an arbitrary non-top square $Q' \in \mathcal{D}_i \setminus \mathcal{F}$ such that $\text{Top}(\mathcal{F} \cup \{Q'\}) =$
 26 \mathcal{F} . We claim that

$$x(Q') < x(K_6^\perp). \quad (12)$$

27 Note that Eq. (10) ensures that the square K_6^\perp exists. Since Q' is a non-
 28 top square, we clearly have $x(Q') < x(K_6^\perp)$ if $Q' \in LE(\mathcal{F} \cup \{Q'\})$. We thus
 29 consider the case where $Q' \in UE(\mathcal{F} \cup \{Q'\})$. Then, since Q' is a non-top square,
 30 $|UE(\mathcal{F})| \geq 6$ and $x(Q') < x(K_6^\top)$ hold. Furthermore, $|UE(\mathcal{F})| \geq 6$ implies that
 31 Eq. (11) holds, and hence by Eq. (3) we have $x(Q') < x(K_6^\perp)$. Therefore, in
 32 either case, Eq. (12) holds.

33 Let S_2 and S_3 be the rightmost and the second rightmost squares in $LE(\mathcal{F}) \setminus$
 34 $UE(\mathcal{F})$, respectively. Since either $|UE(\mathcal{F})| \leq 2$ or $x(K_3^\top) < x(K_6^\perp)$ holds, at

1 most two squares in $UE(\mathcal{F})$ can appear also in $K_1^\perp, K_2^\perp, \dots, K_6^\perp$. Furthermore,
2 $S_1 = K_1^\perp = K_1^\top$. Therefore, we have $S_2 \in \{K_2^\perp, K_3^\perp\}$ and $S_3 \in \{K_3^\perp, K_4^\perp\}$. We
3 consider the following two sub-cases.

4 **Case 2-1:** S_3 is in $UE(LE(\mathcal{F}) \setminus UE(\mathcal{F}))$.

5 In this case, we show that S_2 is stable in \mathcal{F} , and hence we set $K(\mathcal{F}) = S_2$.
6 By Lemma 3.2 it suffices to show that $Q' \notin \Delta(\mathcal{F} \cup \{Q'\}, S_2)$ for every square
7 $Q' \in \mathcal{D}_i \setminus \mathcal{F}$ such that $\text{Top}(\mathcal{F} \cup \{Q'\}) = \mathcal{F}$.

8 We first show that $Q' \notin L\Delta(\mathcal{F} \cup \{Q'\}, S_2)$. Since $S_2 \in \{K_2^\perp, K_3^\perp\}$, by Eq.
9 (12) we have

$$x(Q') < x(K_6^\perp) < x(K_5^\perp) < x(K_4^\perp) < x(S_2).$$

10 By Lemma 4.3 every point in $Q' \cap S_2 \cap R_{i-1}$ is covered by at least five squares,
11 and hence is contained in $A_{\geq 3}((\mathcal{F} \cup \{Q'\}) \setminus \{S_2\})$. By Lemma 4.4 we thus have
12 $Q' \notin L\Delta(\mathcal{F} \cup \{Q'\}, S_2)$, as required.

13 We then show that $Q' \notin U\Delta(\mathcal{F} \cup \{Q'\}, S_2)$. Since $S_3 \in \{K_3^\perp, K_4^\perp\}$ and
14 $x(S_3) < x(S_2)$, by Eq. (12) we have $x(Q') < x(S_3) < x(S_2)$. Since $S_3 \in$
15 $UE(LE(\mathcal{F}) \setminus UE(\mathcal{F}))$, by Lemma 4.2 every point in $Q' \cap S_2 \cap R_i$ is covered
16 by at least three squares. Moreover, since $S_2 \notin UE(\mathcal{F})$, by Lemma 4.1 every
17 point in $Q' \cap S_2 \cap R_i$ is covered by at least one square in $UE(\mathcal{F})$. Thus, in
18 total, every point in $Q' \cap S_2 \cap R_i$ is covered by at least four squares in \mathcal{F} , and
19 hence is contained in $A_{\geq 3}((\mathcal{F} \cup \{Q'\}) \setminus \{S_2\})$. By Lemma 4.4 we thus have
20 $Q' \notin U\Delta(\mathcal{F} \cup \{Q'\}, S_2)$, as required.

21 **Case 2-2:** S_3 is not in $UE(LE(\mathcal{F}) \setminus UE(\mathcal{F}))$.

22 In this case, we show that S_3 is stable in \mathcal{F} , and hence we set $K(\mathcal{F}) = S_3$.
23 By Lemma 3.2 it suffices to show that $Q' \notin \Delta(\mathcal{F} \cup \{Q'\}, S_3)$ for every square
24 $Q' \in \mathcal{D}_i \setminus \mathcal{F}$ such that $\text{Top}(\mathcal{F} \cup \{Q'\}) = \mathcal{F}$.

25 We first show that $Q' \notin L\Delta(\mathcal{F} \cup \{Q'\}, S_3)$. Since $S_3 \in \{K_3^\perp, K_4^\perp\}$, by Eq.
26 (12) we have

$$x(Q') < x(K_6^\perp) < x(K_5^\perp) < x(S_3).$$

27 By Lemma 4.3 every point in $Q' \cap S_3 \cap R_{i-1}$ is covered by at least four squares,
28 and hence is contained in $A_{\geq 3}((\mathcal{F} \cup \{Q'\}) \setminus \{S_3\})$. By Lemma 4.4 we thus have
29 $Q' \notin L\Delta(\mathcal{F} \cup \{Q'\}, S_3)$, as required.

30 We then show that $Q' \notin U\Delta(\mathcal{F} \cup \{Q'\}, S_3)$. Since $S_3 \notin UE(LE(\mathcal{F}) \setminus UE(\mathcal{F}))$,
31 by applying Lemma 4.1 to $LE(\mathcal{F}) \setminus UE(\mathcal{F})$, every point in $Q' \cap S_3 \cap R_i$ is covered
32 by at least one square X in $UE(LE(\mathcal{F}) \setminus UE(\mathcal{F}))$. Moreover, since $S_3 \notin UE(\mathcal{F})$,
33 by applying Lemma 4.1 to \mathcal{F} , every point in $Q' \cap S_3 \cap R_i$ is covered by at least
34 one square Y in $UE(\mathcal{F})$. Note that $X \neq Y$ since $X \in UE(LE(\mathcal{F}) \setminus UE(\mathcal{F}))$ and
35 $Y \in UE(\mathcal{F})$. Thus, in total, every point in $Q' \cap S_3 \cap R_i$ is covered by at least
36 four squares (Q', S_3, X, Y) , and hence is contained in $A_{\geq 3}((\mathcal{F} \cup \{Q'\}) \setminus \{S_3\})$.
37 By Lemma 4.4 we thus have $Q' \notin U\Delta(\mathcal{F} \cup \{Q'\}, S_3)$, as required. \square

38 4.2. Proof of Lemma 3.5

39 We first give an auxiliary lemma which states that at least one of \mathcal{F}_i and
40 \mathcal{F}_{i+1} is safe for the other for each $i \in \{1, \dots, k\}$, and then give the proof of
41 Lemma 3.5.

1 4.2.1. Auxiliary lemma

2 Let \mathcal{F} be a feasible square set on \mathcal{D} , and let \mathcal{C} be a square set in $\mathfrak{C}(\mathcal{F})$. For
3 each $i \in \{1, \dots, k+1\}$, let $ux(\mathcal{C}_i)$ be the x -coordinate of the leftmost point of
4 the area $R_i \cap K(\mathcal{F}_i) \cap (A_1(\mathcal{C}_i) \cup A_2(\mathcal{C}_i))$, while let $lx(\mathcal{C}_i)$ be the x -coordinate of
5 the leftmost point of the area $R_{i-1} \cap K(\mathcal{F}_i) \cap (A_1(\mathcal{C}_i) \cup A_2(\mathcal{C}_i))$. Remember that
6 no horizontal side of a square is on the same line as the horizontal boundary of
7 any ribbon, and that $A_1(\mathcal{C}_i) \cap S \neq \emptyset$ for every square $S \in \mathcal{C}_i$. Therefore, $ux(\mathcal{C}_i)$
8 and $lx(\mathcal{C}_i)$ are well-defined. Since $K(\mathcal{F}_i)$ is stable in \mathcal{F}_i , we see that $ux(\mathcal{C}_i)$
9 is invariant under the choice of $\mathcal{C} \in \mathfrak{C}(\mathcal{F})$. Thus, we also write $ux(\mathcal{F}_i)$ to mean
10 $ux(\mathcal{C}_i)$ for any $\mathcal{C} \in \mathfrak{C}(\mathcal{F})$. The same applies to $lx(\mathcal{F}_i)$.

11 We first give the following lemma.

12 **Lemma 4.8.** *Let \mathcal{F}_i be a feasible square set on \mathcal{D}_i . Let $\mathcal{C} \subseteq \mathcal{D}_i$ be any square
13 set in $\mathfrak{C}_i(\mathcal{F}_i)$, and Q be a non-top square of \mathcal{C} . Then,*

- 14 (a) *every point $(x, y) \in Q \cap R_i \cap (A_1(\mathcal{C}) \cup A_2(\mathcal{C}))$ satisfies $x < ux(\mathcal{F}_i)$; and*
15 (b) *every point $(x, y) \in Q \cap R_{i-1} \cap (A_1(\mathcal{C}) \cup A_2(\mathcal{C}))$ satisfies $x < lx(\mathcal{F}_i)$.*

16 **PROOF.** We show that (a) holds; the proof for (b) is symmetric.

17 Suppose for a contradiction that there exists a point $(x', y') \in Q \cap R_i \cap$
18 $(A_1(\mathcal{C}) \cup A_2(\mathcal{C}))$ which satisfies $x' \geq ux(\mathcal{F}_i)$. Since the square $K(\mathcal{F}_i)$ is stable
19 in \mathcal{F}_i , no point in $K(\mathcal{F}_i) \cap Q$ is contained in $A_1(\mathcal{C}) \cup A_2(\mathcal{C})$. Therefore, we have

$$K(\mathcal{F}_i) \cap Q \cap R_i \cap (A_1(\mathcal{C}) \cup A_2(\mathcal{C})) = \emptyset, \quad (13)$$

20 and hence (x', y') is not contained in $K(\mathcal{F}_i)$. Since Q is a non-top square of \mathcal{C}
21 and $K(\mathcal{F}_i)$ is a top square of \mathcal{C} which is selected as in the proof of Lemma 3.3,
22 we have $x(Q) < x(K(\mathcal{F}_i))$. Since $x' \leq x(Q)$ and $x(K(\mathcal{F}_i)) - 1 \leq ux(\mathcal{F}_i)$, we
23 then have

$$x(K(\mathcal{F}_i)) - 1 \leq ux(\mathcal{F}_i) \leq x' \leq x(Q) < x(K(\mathcal{F}_i)). \quad (14)$$

24 By Eq. (14) we have $x(K(\mathcal{F}_i)) - 1 \leq x' < x(K(\mathcal{F}_i))$. Since (x', y') is not
25 contained in $K(\mathcal{F}_i)$ and is contained in R_i , we have $y' > y(K(\mathcal{F}_i))$. Notice
26 that by Eq. (14) we have $x(Q) - 1 \leq ux(\mathcal{F}_i) \leq x(Q)$. Then, Q contains any
27 point $(ux(\mathcal{F}_i), y'')$ in $K(\mathcal{F}_i)$ which is in $R_i \cap K(\mathcal{F}_i) \cap (A_1(\mathcal{C}_i) \cup A_2(\mathcal{C}_i))$. This
28 contradicts Eq. (13). \square

29 Let \mathcal{F} be a feasible square set on \mathcal{D} . Then, for each $i \in \{2, \dots, k\}$, \mathcal{F}_{i-1} , \mathcal{F}_i
30 and \mathcal{F}_{i+1} are feasible square sets on \mathcal{D}_{i-1} , \mathcal{D}_i and \mathcal{D}_{i+1} , respectively. We say
31 that \mathcal{F}_i is *safe for \mathcal{F}_{i+1}* if $\Delta(\mathcal{C}_i \cup \mathcal{C}_{i+1}, K(\mathcal{F}_i)) \subset \mathcal{F}_i \cup \mathcal{F}_{i+1}$ for any square set \mathcal{C} in
32 $\mathfrak{C}(\mathcal{F})$. Similarly, we say that \mathcal{F}_i is *safe for \mathcal{F}_{i-1}* if $\Delta(\mathcal{C}_{i-1} \cup \mathcal{C}_i, K(\mathcal{F}_i)) \subset \mathcal{F}_{i-1} \cup \mathcal{F}_i$
33 for any square set $\mathcal{C} \in \mathfrak{C}(\mathcal{F})$. For the sake of notational convenience, let $\mathcal{D}_0 = \emptyset$
34 and $\mathcal{D}_{k+2} = \emptyset$; \mathcal{F}_1 is always safe for \mathcal{F}_0 ; and \mathcal{F}_{k+1} is always safe for \mathcal{F}_{k+2} .
35 Since each ribbon is of height 1 and each unit square is of side length 1, the
36 square $K(\mathcal{F}_i) \in \mathcal{D}_i$ intersects squares in $\mathcal{D}_{i-1} \cup \mathcal{D}_i \cup \mathcal{D}_{i+1}$ only. Therefore, for
37 $i \in \{1, \dots, k+1\}$, \mathcal{F}_i is safe for \mathcal{F} if and only if \mathcal{F}_i is safe for both \mathcal{F}_{i-1} and
38 \mathcal{F}_{i+1} .

39 Then, Lemma 4.8 gives the following lemma.

1 **Lemma 4.9.** *Let \mathcal{F} be a feasible square set on \mathcal{D} . Then, for each $i \in \{1, \dots, k\}$,*
 2 *the following (a) and (b) hold:*

- 3 (a) \mathcal{F}_i is safe for \mathcal{F}_{i+1} if $lx(\mathcal{F}_{i+1}) < ux(\mathcal{F}_i)$; and
 4 (b) \mathcal{F}_{i+1} is safe for \mathcal{F}_i if $ux(\mathcal{F}_i) < lx(\mathcal{F}_{i+1})$.

5 **PROOF.** We show that (a) holds: If $lx(\mathcal{F}_{i+1}) < ux(\mathcal{F}_i)$, then $\Delta(\mathcal{C}_i \cup$
 6 $\mathcal{C}_{i+1}, K(\mathcal{F}_i)) \subset \mathcal{F}_i \cup \mathcal{F}_{i+1}$ for any square set \mathcal{C} in $\mathfrak{C}(\mathcal{F})$. (The proof for (b)
 7 is symmetric.)

8 Consider an arbitrary square set $\mathcal{C} \in \mathfrak{C}(\mathcal{F})$, and let Q be a square in $\mathcal{C}_i \cup \mathcal{C}_{i+1}$
 9 such that $Q \not\subset \mathcal{F}_i \cup \mathcal{F}_{i+1}$. We will show that $Q \not\subset \Delta(\mathcal{C}_i \cup \mathcal{C}_{i+1}, K(\mathcal{F}_i))$. Note
 10 that, however, we have $Q \not\subset \Delta(\mathcal{C}_i \cup \mathcal{C}_{i+1}, K(\mathcal{F}_i))$ if $Q \in \mathcal{C}_i$, because the square
 11 $K(\mathcal{F}_i)$ is stable in \mathcal{F}_i .

12 We thus consider the case where $Q \in \mathcal{C}_{i+1}$. Since $K(\mathcal{F}_i) \in \mathcal{C}_i$, the intersection
 13 $K(\mathcal{F}_i) \cap Q$ is contained in R_i . Therefore, similarly to Lemma 4.4, we have
 14 $Q \not\subset \Delta(\mathcal{C}_i \cup \mathcal{C}_{i+1}, K(\mathcal{F}_i))$ if any point in $Q \cap K(\mathcal{F}_i) \cap R_i$ is contained in $A_{\geq 3}(\mathcal{C}_i \cup$
 15 $\mathcal{C}_{i+1} \setminus \{K(\mathcal{F}_i)\})$.

16 Since $K(\mathcal{F}_i) \in \mathcal{C}_i$, if a point in $Q \cap K(\mathcal{F}_i) \cap R_i$ is contained in $A_{\geq 3}(\mathcal{C}_{i+1})$,
 17 then the point is contained in $A_{\geq 3}(\mathcal{C}_i \cup \mathcal{C}_{i+1} \setminus \{K(\mathcal{F}_i)\})$. Therefore, we consider
 18 a point (x', y') in $Q \cap K(\mathcal{F}_i) \cap R_i$ which is contained in $A_1(\mathcal{C}_{i+1}) \cup A_2(\mathcal{C}_{i+1})$;
 19 and hence (x', y') is contained in at least one square in \mathcal{C}_{i+1} . Then, by Lemma
 20 4.8 we have $x' < lx(\mathcal{F}_{i+1})$ and hence $x' < ux(\mathcal{F}_i)$. This implies that the point
 21 (x', y') is contained in at least three squares in \mathcal{C}_i (one of which is $K(\mathcal{F}_i)$). Thus,
 22 the point (x', y') is contained in $A_{\geq 3}(\mathcal{C}_i \cup \mathcal{C}_{i+1} \setminus \{K(\mathcal{F}_i)\})$. \square

23 4.2.2. Proof of Lemma 3.5

24 Since no vertical side of a square is on the same line as the vertical side
 25 of another square, $ux(\mathcal{F}_i) \neq lx(\mathcal{F}_{i+1})$ for each $i \in \{1, \dots, k\}$. Therefore, by
 26 Lemma 4.9 at least one of \mathcal{F}_i and \mathcal{F}_{i+1} is safe for the other. Remember that \mathcal{F}_1
 27 is always safe for \mathcal{F}_0 , and that \mathcal{F}_{k+1} is always safe for \mathcal{F}_{k+2} . Therefore, there
 28 exists at least one index $q \in \{1, \dots, k+1\}$, such that \mathcal{F}_q is safe for both \mathcal{F}_{q-1}
 29 and \mathcal{F}_{q+1} . Then, \mathcal{F}_q is safe for \mathcal{F} . \square

30 5. Budgeted version

31 In this section, we give the following theorem.

32 **Theorem 5.1.** *For any fixed constant $\varepsilon > 0$, there is a polynomial-time $(1+\varepsilon)$ -*
 33 *approximation algorithm for the budgeted unique unit-square coverage problem.*

34 We give a sketch how to adapt the algorithm above to the budgeted unique
 35 unit-square coverage problem. To this end, we first describe the adaptation to
 36 give an optimal solution to $\langle \mathcal{P} \cap G, \mathcal{D} \rangle$ in pseudo-polynomial time when budget,
 37 cost, and profit are all integers.

38 We keep the same strategy, but for the dynamic programming, we slightly
 39 change the definition of f . In the budgeted version, $\text{profit}(\mathcal{P}, \mathcal{C})$ means the total
 40 profit of the points in \mathcal{P} that are uniquely covered by \mathcal{C} , and $\text{cost}(\mathcal{C})$ means the

1 total cost of the squares in \mathcal{C} . Let $X = \sum_{p \in \mathcal{P}} \text{profit}(p)$, then $\text{profit}(\mathcal{P}, \mathcal{C}) \leq X$
2 for any square set $\mathcal{C} \subseteq \mathcal{D}$. For a feasible square set $\mathcal{F} \subseteq \mathcal{D}$ and an integer $x \in$
3 $\{0, \dots, X\}$, let $g(\mathcal{F}, x)$ be the minimum total cost of squares in a set $\mathcal{C} \in \mathfrak{C}(\mathcal{F})$
4 such that the total profit of uniquely covered points in $\mathcal{P} \cap G$ by \mathcal{C} is at least x ,
5 that is,

$$g(\mathcal{F}, x) = \min\{\text{cost}(\mathcal{C}) \mid \mathcal{C} \in \mathfrak{C}(\mathcal{F}) \text{ and } \text{profit}(\mathcal{P} \cap G, \mathcal{C}) \geq x\}.$$

6 If there is no square set $\mathcal{C} \in \mathfrak{C}(\mathcal{F})$ such that $\text{profit}(\mathcal{P} \cap G, \mathcal{C}) \geq x$, then let
7 $g(\mathcal{F}, x) = +\infty$. Then, the optimal value $\text{OPT}(\mathcal{P} \cap G, \mathcal{D})$ for the budgeted
8 version on $\langle \mathcal{P} \cap G, \mathcal{D} \rangle$ can be computed as

$$\text{OPT}(\mathcal{P} \cap G, \mathcal{D}) = \max\{x \mid 0 \leq x \leq X, g(\mathcal{F}, x) \leq B\}.$$

9 We proceed along the same way as the algorithm in Section 3.6, except for the
10 update formula (2) that should be replaced by

$$g(\mathcal{F}, x) := \min\{g(\mathcal{F}', y) \mid \mathcal{F}' \text{ is a child of } \mathcal{F}, y + z(\mathcal{F}, K(\mathcal{F})) \geq x\} + \text{cost}(K(\mathcal{F})),$$

11 where $z(\mathcal{F}, K(\mathcal{F}))$ means the difference of the total profit of uniquely covered
12 points in $\mathcal{P} \cap G$ caused by adding the square $K(\mathcal{F})$ to $\mathcal{F} \setminus \{K(\mathcal{F})\}$. This way,
13 we obtain an optimal solution to $\langle \mathcal{P} \cap G, \mathcal{D} \rangle$ for a group G consisting of at
14 most k consecutive ribbons. Note that the blowup in the running time is only
15 polynomial in X .

16 Let R_1, R_2, \dots, R_t be the ribbons in R_W ordered from bottom to top. For
17 each $j \in \{0, \dots, k\}$, let R_W^j be the set of groups G_1, G_2, \dots , each of which
18 consists of at most k ribbons, obtained from R_W by deleting the ribbons R_i if
19 and only if $i = j \bmod k + 1$, as illustrated in Figure 2. We now explain how
20 to obtain a solution to the problem on $\langle \mathcal{P} \cap R_W^j, \mathcal{D} \rangle$. The adapted algorithm
21 above can solve the problem on each group G_l in R_W^j , and hence suppose that
22 we have computed $g(\mathcal{F}, x)$ for each group G_l and all integers $x \in \{0, \dots, X\}$.
23 Then, obtaining a solution to $\langle \mathcal{P} \cap R_W^j, \mathcal{D} \rangle$ can be regarded as solving an instance
24 of the multiple-choice knapsack problem [5, 18], as follows: The capacity of the
25 knapsack is equal to the budget B ; each $g(\mathcal{F}, x)$ in G_l and $x \in \{0, 1, \dots, X\}$ have
26 a corresponding item with profit x and cost $g(\mathcal{F}, x)$; and the items corresponding
27 to G_l form a class, from which at most one item can be packed into the knapsack.
28 The multiple-choice knapsack problem can be solved in pseudo-polynomial time
29 which polynomially depends on X [5, 18], and hence we can obtain an optimal
30 solution to $\langle \mathcal{P} \cap R_W^j, \mathcal{D} \rangle$, $0 \leq j \leq k$, in pseudo-polynomial time.

31 Then, by the standard scale-and-round technique (as used for the ordinary
32 knapsack problem) [5, 18], for any fixed constant $\varepsilon' > 0$, we obtain a $(1 + \varepsilon')$ -
33 approximate solution to $\langle \mathcal{P} \cap R_W^j, \mathcal{D} \rangle$ for each $j \in \{0, \dots, k\}$. Overall, we
34 can obtain such an approximate solution to each of the $k + 1$ subinstances
35 $\langle \mathcal{P} \cap R_W^j, \mathcal{D} \rangle$, $0 \leq j \leq k$, in polynomial time. By taking the best one, we can
36 obtain a $(1 + \varepsilon)$ -approximate solution to $\langle \mathcal{P}, \mathcal{D} \rangle$ for any fixed constant $\varepsilon > 0$, by
37 choosing ε' appropriately.

6. Conclusion

The PTAS in this paper combines the well-known shifting strategy [1, 13] and a novel dynamic programming algorithm to solve the problem restricted to regions of constant height, and answers a question by van Leeuwen [21]. The generality of the approach enables us to solve the budgeted version, too.

In a sister paper [16], we give a polynomial-time $(2+4/\sqrt{3}+\varepsilon)$ -approximation algorithm for the unique *unit-disk* coverage problem for any fixed constant $\varepsilon > 0$, thus improving the approximation ratio of 18 by Erlebach and van Leeuwen [9]. The basic idea is similar to our PTAS in this paper, but the situation is much more complicated for unit disks.

The reader may wonder why the technique developed in this paper cannot readily yield a PTAS for the unit disk case. The current technique involves two aspects; one is the partition of the whole plane to adapt the shifting strategy, and the other is a polynomial-time algorithm for each group. However, these two aspects may affect each other in the following sense. If we would stick to a partition of the whole plane to obtain a PTAS, then we were not able to develop a polynomial-time algorithm for each group. If we would want to have a polynomial-time algorithm for each group, then the partition could not be good enough to give a better approximation ratio. Indeed, for the unit disks, as treated in our sister paper [16], we have a different way of partitioning the whole plane, so that the polynomial-time algorithm can be developed.³ Then, the approximation ratio got worse, and we only have a $(2+4/\sqrt{3}+\varepsilon)$ -approximation algorithm, not a PTAS.

The running time of our PTAS is a polynomial of degree depending on $1/\varepsilon$. It is desirable to obtain a PTAS such that the degree of its polynomial running time does not depend on $1/\varepsilon$: Such a PTAS is called an efficient PTAS (EPTAS). The existence of an EPTAS would be excluded by showing W[1]-hardness (unless $\text{FPT} = \text{W}[1]$) [2, 3], but the unique coverage problem is fixed-parameter tractable [19], thus unlikely to be W[1]-hard. The existence of an EPTAS is left open.

Acknowledgments

The authors thank anonymous referees of the preliminary version and of this journal version for their helpful suggestions. This work is partially supported by Grant-in-Aid for Scientific Research (KAKENHI) including 24106004, 24106005, 24220003, 24700008, 25330003, 26330009, 15H00853, 15K00009, and by the Funding Program for World-Leading Innovative R&D on Science and Technology, Japan.

³This sentence contains some inaccuracy since we do not really develop a polynomial-time algorithm for each group, but rather we design a PTAS for each group.
