## Abstract

Suppose that we are given two independent sets  $I_b$  and  $I_r$  of a graph such that  $|I_b| = |I_r|$ , and imagine that a token is placed on each vertex in  $I_b$ . Then, the SLIDING TOKEN problem is to determine whether there exists a sequence of independent sets which transforms  $I_b$  into  $I_r$  so that each independent set in the sequence results from the previous one by sliding exactly one token along an edge in the graph. This problem is known to be PSPACE-complete even for planar graphs, and also for bounded treewidth graphs. In this paper, we thus study the problem restricted to trees, and give the following three results: (1) the decision problem is solvable in linear time; (2) for a yes-instance, we can find in quadratic time an actual sequence of independent sets between  $I_b$  and  $I_r$  whose length (i.e., the number of token-slides) is quadratic; and (3) there exists an infinite family of instances on paths for which any sequence requires quadratic length.

*Keywords:* combinatorial reconfiguration, graph algorithm, independent set, sliding token, tree

---

## 1. Introduction

Recently, *reconfiguration problems* **have attracted** the attention in the field of theoretical computer science. The problem arises when we wish to find a step-by-step transformation between two feasible solutions of a problem such that all intermediate results are also feasible and each step **conforms to** a fixed reconfiguration rule (i.e., an adjacency relation defined on feasible solutions of the original problem). This kind of reconfiguration problem has been studied

Figure 1: A sequence  $\langle I_1, I_2, \dots, I_5 \rangle$  of independent sets of the same graph, where the vertices in independent sets are depicted by large black circles (tokens).

1 extensively for several well-known problems, including INDEPENDENT SET [2, 5,  
 2 7, 11, 12, 14, 16, 20, 22, 23, 25], SATISFIABILITY [10, 21], SET COVER, CLIQUE,  
 3 MATCHING [14], VERTEX-COLORING [3, 6, 8, 25], LIST EDGE-COLORING [15, 18],  
 4 LIST  $L(2, 1)$ -LABELING [17], SUBSET SUM [13], SHORTEST PATH [4, 19], and so  
 5 on. (See also a recent survey [24].)

### 6 1.1. SLIDING TOKEN

7 The SLIDING TOKEN problem was introduced by Hearn and Demaine [11] as  
 8 a one-player game, which can be seen as a reconfiguration problem for INDE-  
 9 PENDENT SET. Recall that an *independent set* of a graph  $G$  is a **vertex subset**  
 10 of  $G$  in which no two vertices are adjacent. (Figure 1 depicts five different in-  
 11 dependent sets in the same graph.) Suppose that we are given two independent  
 12 sets  $I_b$  and  $I_r$  of a graph  $G = (V, E)$  such that  $|I_b| = |I_r|$ , and imagine that a  
 13 token (coin) is placed on each vertex in  $I_b$ . Then, the SLIDING TOKEN problem  
 14 is to determine whether there exists a sequence  $\langle I_1, I_2, \dots, I_\ell \rangle$  of independent  
 15 sets of  $G$  such that

- 16 (a)  $I_1 = I_b$ ,  $I_\ell = I_r$ , and  $|I_i| = |I_b| = |I_r|$  for all  $i$ ,  $1 \leq i \leq \ell$ ; and  
 17 (b) for each  $i$ ,  $2 \leq i \leq \ell$ , there is an edge  $\{u, v\}$  in  $G$  such that  $I_{i-1} \setminus I_i = \{u\}$   
 18 and  $I_i \setminus I_{i-1} = \{v\}$ , that is,  $I_i$  can be obtained from  $I_{i-1}$  by sliding exactly  
 19 one token on a vertex  $u \in I_{i-1}$  to its adjacent vertex  $v$  along  $\{u, v\} \in E$ .

20 Such a sequence is called a *reconfiguration sequence* between  $I_b$  and  $I_r$ . Figure 1  
 21 illustrates a reconfiguration sequence  $\langle I_1, I_2, \dots, I_5 \rangle$  of independent sets which  
 22 transforms  $I_b = I_1$  into  $I_r = I_5$ . Hearn and Demaine proved that SLIDING  
 23 TOKEN is PSPACE-complete for planar graphs, as an example of the application  
 24 of their **tool**, called the nondeterministic constraint logic model, which can be  
 25 used to prove PSPACE-hardness of many puzzles and games [11], [12, Sec. 9.5].

### 26 1.2. Related and known results

27 As the (ordinary) INDEPENDENT SET problem is a key problem among thou-  
 28 sands of NP-complete problems, SLIDING TOKEN plays an important role since  
 29 several PSPACE-hardness results have been proved using reductions from it.  
 30 In addition, reconfiguration problems for INDEPENDENT SET (ISRECONF, for  
 31 short) have been studied under different reconfiguration rules, as follows.

- 32 • *Token Sliding* (TS rule) [6, 7, 11, 12, 20, 25]: This rule corresponds to  
 33 SLIDING TOKEN, that is, we can slide a single token only along an edge of  
 34 a graph.

Figure 2: **Two distinct independent sets  $I_b$  and  $I_r$  of the same star. This is a yes-instance for ISRECONF under the TJ rule, but is a no-instance for the SLIDING TOKEN problem.**

- 1 • *Token Jumping* (TJ rule) [7, 16, 20, 25]: A single token can “jump” to  
2 any vertex (including a non-adjacent one) if it results in an independent  
3 set.
- 4 • *Token Addition and Removal* (TAR rule) [2, 5, 14, 20, 22, 23, 25]: We can  
5 either add or remove a single token at a time if it results in an independent  
6 set of cardinality at least a given **threshold**. Therefore, under the TAR  
7 rule, independent sets in the sequence do not have the same cardinality.

8 We note that the existence of a desired sequence depends deeply on the recon-  
9 figuration rules. (See Figure 2 for example.) However, ISRECONF is PSPACE-  
10 complete under any of the three reconfiguration rules for planar graphs [6,  
11 11, 12], for perfect graphs [20], and for bounded bandwidth graphs [25]. The  
12 PSPACE-hardness implies that, unless  $NP = PSPACE$ , there exists an instance  
13 of SLIDING TOKEN which requires a super-polynomial number of token-slides  
14 even in a minimum-length reconfiguration sequence. In such a case, tokens  
15 should make “detours” to avoid violating independence. (For example, see the  
16 token placed on the vertex  $w$  in Figure 1(a); it is moved twice even though  
17  $w \in I_b \cap I_r$ .)

18 We here explain only the results which are strongly related to this paper,  
19 that is, SLIDING TOKEN on trees; see the references above for the other results.

### 20 1.2.1. Results for TS rule (SLIDING TOKEN)

21 Kamiński et al. [20] gave a linear-time algorithm to solve SLIDING TOKEN  
22 for cographs (also known as  $P_4$ -free graphs). They also showed that, for any  
23 yes-instance on cographs, two given independent sets  $I_b$  and  $I_r$  have a reconfi-  
24 guration sequence such that no token makes a detour.

25 Very recently, Bonsma et al. [7] proved that SLIDING TOKEN can be solved in  
26 polynomial time for claw-free graphs. Note that neither cographs nor claw-free  
27 graphs contain trees as a (proper) subclass. Thus, the complexity status for  
28 trees was open under the TS rule.

### 29 1.2.2. Results for trees

30 In contrast to the TS rule, it is known that ISRECONF can be solved in  
31 linear time under the TJ and TAR rules for even-hole-free graphs [20], which  
32 include trees. Indeed, the answer is always “yes” under the two rules when  
33 restricted to even-hole-free graphs (as long as two given independent sets have

1 the same cardinality for the TJ rule.) Furthermore, tokens never make detours  
2 in even-hole-free graphs under the TJ and TAR rules.

3 On the other hand, under the TS rule, tokens are required to make detours  
4 even in trees. (See Figure 1.) In addition, there are no-instances for trees under  
5 the TS rule. (See Figure 2.) These make the problem much more complicated,  
6 and we think they are the main reasons why SLIDING TOKEN for trees was  
7 **unsolved, even though this is certainly a natural question under** the recent  
8 intensive algorithmic research on ISRECONF [2, 5, 7, 16, 20, 23].

### 9 1.3. Our contribution

10 In this paper, we first prove that the SLIDING TOKEN problem is solvable  
11 in  $O(n)$  time for any tree  $T$  with  $n$  vertices. Therefore, we can conclude that  
12 ISRECONF for trees is in P (indeed, solvable in linear time) under any of the  
13 three reconfiguration rules.

14 It is remarkable that there exists an infinite family of instances on paths  
15 for which any reconfiguration sequence requires  $\Omega(n^2)$  length, although we can  
16 decide if it is a yes-instance in  $O(n)$  time. **For example, consider a path**  
17  **$(v_1, v_2, \dots, v_{8k})$  with  $n = 8k$  vertices for any positive integer  $k$ , and let  $I_b =$**   
18  **$\{v_1, v_3, v_5, \dots, v_{2k-1}\}$  and  $I_r = \{v_{6k+2}, v_{6k+4}, \dots, v_{8k}\}$ . In this yes-instance,**  
19 **any token must be slid  $\Theta(n)$  times, and hence any reconfiguration sequence re-**  
20 **quires  $\Theta(n^2)$  length to slide them all.** As the second result of this paper, we  
21 give an  $O(n^2)$ -time algorithm which finds an actual reconfiguration sequence of  
22 length  $O(n^2)$  between two given independent sets for a yes-instance.

23 Since the treewidth of any graph  $G$  can be bounded by the bandwidth of  $G$ ,  
24 the result of [25] implies that SLIDING TOKEN is PSPACE-complete for bounded  
25 treewidth graphs. (See [1] for the definition of treewidth.) Thus, there exists  
26 an instance on bounded treewidth graphs which requires a super-polynomial  
27 number of token-slides even in a minimum-length reconfiguration sequence un-  
28 less  $\text{NP} = \text{PSPACE}$ . Therefore, it is interesting that any yes-instance on a  
29 tree, whose treewidth is one, has an  $O(n^2)$ -length reconfiguration sequence even  
30 though trees require **detours for transformations**.

31 An early version of the paper has been presented in [9]. However, we note  
32 that the running time of our algorithm was improved from quadratic [9] to  
33 linear.

### 34 1.4. Technical overview

35 We here explain our main ideas; formal descriptions will be given later.

36 We say that a token on a vertex  $v$  is “rigid” under an independent set  $I$  of a  
37 tree  $T$  if it cannot be slid at all, that is,  $v \in I'$  holds for *any* independent set  $I'$   
38 of  $T$  which is reconfigurable from  $I$ . (For example, **the** four tokens in Figure 2  
39 are rigid.) Our algorithm is based on the following two key points.

- 40 (1) In Lemma 1, we will give a simple but non-trivial characterization of rigid  
41 tokens, based on which we can find all rigid tokens of two given independ-  
42 ent sets  $I_b$  and  $I_r$  in  $O(n)$  time. Note that, if  $I_b$  and  $I_r$  have different  
43 placements of rigid tokens, then it is a no-instance (Observation 1).

Figure 3: Subtree  $T_v^u$  in the whole tree  $T$ .

- 1 (2) Otherwise, we obtain a forest by deleting the vertices with rigid tokens  
2 together with their neighbors (Lemma 5). We will prove in Lemma 6 that  
3 the answer is “yes” as long as each tree in the forest contains the same  
4 number of tokens in  $I_b$  and  $I_r$ .

## 5 2. Preliminaries

6 In this section, we introduce some basic terms and notation.

### 7 2.1. Graph notation

8 In the SLIDING TOKEN problem, we may assume without loss of generality  
9 that graphs are simple and connected. For a graph  $G$ , we sometimes denote by  
10  $V(G)$  and  $E(G)$  the vertex set and edge set of  $G$ , respectively.

11 In a graph  $G$ , a vertex  $w$  is said to be a *neighbor* of a vertex  $v$  if  $\{v, w\} \in$   
12  $E(G)$ . For a vertex  $v$  in  $G$ , let  $N(G, v) = \{w \in V(G) \mid \{v, w\} \in E(G)\}$ ,  
13 and let  $N[G, v] = N(G, v) \cup \{v\}$ . For a subset  $S \subseteq V(G)$ , we simply write  
14  $N[G, S] = \bigcup_{v \in S} N[G, v]$ . For a vertex  $v$  of  $G$ , we denote by  $\deg_G(v)$  the degree  
15 of  $v$  in  $G$ , that is,  $\deg_G(v) = |N(G, v)|$ . For a subgraph  $G'$  of a graph  $G$ , we  
16 denote by  $G \setminus G'$  the subgraph of  $G$  induced by the vertices in  $V(G) \setminus V(G')$ .

17 Let  $T$  be a tree. For two vertices  $v$  and  $w$  in  $T$ , the unique path between  $v$   
18 and  $w$  is simply called the  *$vw$ -path* in  $T$ . We denote by  $\text{dist}(v, w)$  the number  
19 of edges in the  $vw$ -path in  $T$ . For two **adjacent (and hence distinct)** vertices  $u$   
20 and  $v$  of a tree  $T$ , let  $T_v^u$  be the subtree of  $T$  obtained by regarding  $u$  as the  
21 root of  $T$  and then taking the subtree rooted at  $v$  which consists of  $v$  and all  
22 descendants of  $v$ . (See Figure 3.) It should be noted that  $u$  is not contained in  
23 the subtree  $T_v^u$ .

### 24 2.2. Definitions for SLIDING TOKEN

25 Let  $I_i$  and  $I_j$  be two independent sets of a graph  $G$  such that  $|I_i| = |I_j|$ . If  
26 there exists exactly one edge  $\{u, v\}$  in  $G$  such that  $I_i \setminus I_j = \{u\}$  and  $I_j \setminus I_i = \{v\}$ ,  
27 then we say that  $I_j$  can be obtained from  $I_i$  by *sliding* the token on  $u \in I_i$  to  
28 its adjacent vertex  $v$  along the edge  $\{u, v\}$ , and denote it by  $I_i \leftrightarrow I_j$ . We note  
29 that the tokens are unlabeled, while the vertices in a graph are labeled. We  
30 sometimes omit **saying** (the label of) the vertex on which a token is placed, and  
31 simply say “a token in an independent set  $I$ .”

32 A *reconfiguration sequence* between two independent sets  $I_1$  and  $I_\ell$  of  $G$  is  
33 a sequence  $\langle I_1, I_2, \dots, I_\ell \rangle$  of independent sets of  $G$  such that  $I_{i-1} \leftrightarrow I_i$  for  $i =$   
34  $2, 3, \dots, \ell$ . We sometimes write  $I \in \mathcal{S}$  if an independent set  $I$  of  $G$  appears in the

Figure 4: An independent set  $I$  of a tree  $T$ , where  $t_1, t_2, t_3, t_4$  are  $(T, I)$ -rigid tokens and  $t_5, t_6, t_7$  are  $(T, I)$ -movable tokens. For the subtree  $T'$ , tokens  $t_6, t_7$  are  $(T', I \cap T')$ -rigid.

1 reconfiguration sequence  $\mathcal{S}$ . We write  $I_1 \overset{G}{\rightsquigarrow} I_\ell$  if there exists a reconfiguration  
 2 sequence  $\mathcal{S}$  between  $I_1$  and  $I_\ell$  such that all independent sets  $I \in \mathcal{S}$  satisfy  
 3  $I \subseteq V(G)$ ; we here define the notation emphasized with the graph  $G$ , because  
 4 we will apply this notation to a subgraph of  $G$ . Note that any reconfiguration  
 5 sequence is *reversible*, that is,  $I_1 \overset{G}{\rightsquigarrow} I_\ell$  if and only if  $I_\ell \overset{G}{\rightsquigarrow} I_1$ . The *length*  
 6 of a reconfiguration sequence  $\mathcal{S}$  is defined as the number of independent sets  
 7 contained in  $\mathcal{S}$ . For example, the length of the reconfiguration sequence in  
 8 Figure 1 is 5.

9 Given two independent sets  $I_b$  and  $I_r$  of a graph  $G$ , the SLIDING TOKEN  
 10 problem is to determine whether  $I_b \overset{G}{\rightsquigarrow} I_r$  or not. We may assume without  
 11 loss of generality that  $|I_b| = |I_r|$ ; otherwise the answer is clearly “no.” Note  
 12 that SLIDING TOKEN is a decision problem asking for the existence of a recon-  
 13 figuration sequence between  $I_b$  and  $I_r$ , and hence it does not ask for an actual  
 14 reconfiguration sequence. We always denote by  $I_b$  and  $I_r$  the *initial* and *target*  
 15 independent sets of  $G$ , respectively.

### 16 3. Algorithm for Trees

17 In this section, we give the main result of this paper.

18 **Theorem 1.** *The SLIDING TOKEN problem can be solved in linear time for trees.*

19 As a proof of Theorem 1, we give an  $O(n)$ -time algorithm which solves  
 20 SLIDING TOKEN for a tree with  $n$  vertices.

#### 21 3.1. Rigid tokens

22 In this subsection, we formally define the concept of rigid tokens, and give  
 23 their nice characterization.

24 Let  $T$  be a tree, and let  $I$  be an independent set of  $T$ . We say that a token  
 25 on a vertex  $v \in I$  is  $(T, I)$ -*rigid* if  $v \in I'$  holds for *any* independent set  $I'$  of  $T$   
 26 such that  $I \overset{T}{\rightsquigarrow} I'$ . Conversely, if a token on a vertex  $v \in I$  is not  $(T, I)$ -rigid,  
 27 then it is  $(T, I)$ -*movable*; in other words, there exists an independent set  $I'$   
 28 such that  $v \notin I'$  and  $I \overset{T}{\rightsquigarrow} I'$ . For example, in Figure 4, the tokens  $t_1, t_2, t_3, t_4$   
 29 are  $(T, I)$ -rigid, while the tokens  $t_5, t_6, t_7$  are  $(T, I)$ -movable. Note that, even  
 30 though  $t_6$  and  $t_7$  cannot be slid to any neighbor in  $T$  under  $I$ , we can slide them  
 31 after sliding  $t_5$  downward.

Figure 5: (a) A  $(T, I)$ -rigid token on  $u$ , and (b) a  $(T, I)$ -movable token on  $u$ .

1 We then extend the concept of rigid/movable tokens to subgraphs of  $T$ . For  
2 any subgraph  $T'$  of  $T$ , we denote simply  $I \cap T' = I \cap V(T')$ . Then, a token on  
3 a vertex  $v \in I \cap T'$  is  $(T', I \cap T')$ -rigid if  $v \in J$  holds for *any* independent set  $J$   
4 of  $T'$  such that  $I \cap T' \overset{T'}{\rightsquigarrow} J$ ; otherwise it is  $(T', I \cap T')$ -movable. For example,  
5 in Figure 4, tokens  $t_6$  and  $t_7$  are  $(T', I \cap T')$ -rigid even though they are  $(T, I)$ -  
6 movable in the whole tree  $T$ . Note that, since **the reconfiguration is** restricted  
7 only to the subgraph  $T'$ , we cannot use any vertex (and hence any edge) in  $T \setminus T'$   
8 during the reconfiguration. Furthermore, the **vertex subset**  $J \cup (I \cap (T \setminus T'))$   
9 does not necessarily form an independent set of the whole tree  $T$ .

10 We now give our first key lemma, which gives a characterization of rigid  
11 tokens. (See also Figure 5(a) for the claim (b) below.)

12 **Lemma 1.** *Let  $I$  be an independent set of a tree  $T$ , and let  $u$  be a vertex in  $I$ .*

- 13 (a) *Suppose that  $|V(T)| = |\{u\}| = 1$ . Then, the token on  $u$  is  $(T, I)$ -rigid.*  
14 (b) *Suppose that  $|V(T)| \geq 2$ . Then, the token on  $u$  is  $(T, I)$ -rigid if and only  
15 if, for every neighbor  $v \in N(T, u)$ , there exists a vertex  $w \in I \cap N(T_v^u, v)$   
16 such that the token on  $w$  is  $(T_w^v, I \cap T_w^v)$ -rigid.*

17 **PROOF.** Obviously, the claim (a) holds. In the following, we thus assume that  
18  $|V(T)| \geq 2$  and prove the claim (b).

19 We first show the if direction. **Since we can slide a token only along an edge**  
20 **of  $T$ , if the token  $t$  on  $u$  is not  $(T, I)$ -rigid (and hence is  $(T, I)$ -movable), then**  
21 **it must be slid to some neighbor  $v \in N(T, u)$ . (See Figure 5(a).) However, by**  
22 **the assumption, there exists a vertex  $w \in I \cap N(T_v^u, v)$  such that the token on**  
23  **$w$  is  $(T_w^v, I \cap T_w^v)$ -rigid. We can thus conclude that  $t$  is  $(T, I)$ -rigid.**

24 We then show the only-if direction by taking a contrapositive. Suppose that  
25  $u$  has a neighbor  $v \in N(T, u)$  such that either  $I \cap N(T_v^u, v) = \emptyset$  or all tokens on  
26  $w \in I \cap N(T_v^u, v)$  are  $(T_w^v, I \cap T_w^v)$ -movable. (See Figure 5(b).) Then, we will  
27 prove that the token  $t$  on  $u$  is  $(T, I)$ -movable; in particular, we can slide  $t$  from  $u$   
28 to  $v$ . Since any token  $t'$  on a vertex  $w \in I \cap N(T_v^u, v)$  is  $(T_w^v, I \cap T_w^v)$ -movable, we  
29 can slide  $t'$  to some vertex in  $T_w^v$  via a reconfiguration sequence  $\mathcal{S}_w$  in  $T_w^v$ . Recall  
30 that only the vertex  $v$  is adjacent with a vertex in  $T_w^v$  and  $v \notin I$ . Therefore,  $\mathcal{S}_w$   
31 can be naturally extended to a reconfiguration sequence  $\mathcal{S}$  in the whole tree  $T$   
32 such that  $I' \cap (T \setminus T_w^v) = I \cap (T \setminus T_w^v)$  holds for any independent set  $I' \in \mathcal{S}$   
33 of  $T$ . Apply this process to all tokens on vertices in  $I \cap N(T_v^u, v)$ , and obtain an  
34 independent set  $I''$  of  $T$  such that  $I'' \cap N(T_v^u, v) = \emptyset$ . Then, we can slide the  
35 token  $t$  on  $u$  to  $v$ . Thus,  $t$  is  $(T, I)$ -movable.  $\square$

Figure 6: Illustration for Lemma 2.

1 The following lemma is useful for proving the correctness of our algorithm  
 2 in Section 3.3.

3 **Lemma 2.** *Let  $I$  be an independent set of a tree  $T$  such that all tokens are*  
 4  *$(T, I)$ -movable, and let  $v$  be a vertex such that  $v \notin I$ . Then, there exists at most*  
 5 *one neighbor  $w \in I \cap N(T, v)$  such that the token on  $w$  is  $(T_w^v, I \cap T_w^v)$ -rigid.*

6 **PROOF.** Suppose for a contradiction that there exist two neighbors  $w$  and  $w'$   
 7 in  $I \cap N(T, v)$  such that the tokens on  $w$  and  $w'$  are  $(T_w^v, I \cap T_w^v)$ -rigid and  
 8  $(T_{w'}^v, I \cap T_{w'}^v)$ -rigid, respectively. (See Figure 6.) Since the token  $t$  on  $w$  is  
 9  $(T_w^v, I \cap T_w^v)$ -rigid but is  $(T, I)$ -movable, there is a reconfiguration sequence  $\mathcal{S}_t$   
 10 starting from  $I$  which slides  $t$  to  $v$ . However, before sliding  $t$  to  $v$ ,  $\mathcal{S}_t$  must slide  
 11 the token  $t'$  on  $w'$  to some vertex in  $N(T_{w'}^v, w')$ . This contradicts the assumption  
 12 that  $t'$  is  $(T_{w'}^v, I \cap T_{w'}^v)$ -rigid.  $\square$

### 13 3.2. Linear-time algorithm

14 In this subsection, we describe an algorithm to solve the SLIDING TOKEN  
 15 problem for trees, and estimate its running time; the correctness of the algorithm  
 16 will be proved in Section 3.3.

17 Let  $T$  be a tree with  $n$  vertices, and let  $I_b$  and  $I_r$  be two given independent  
 18 sets of  $T$ . For an independent set  $I$  of  $T$ , we denote by  $R(I)$  the set of all vertices  
 19 in  $I$  on which  $(T, I)$ -rigid tokens are placed. Then, the following algorithm  
 20 determines whether  $I_b \stackrel{T}{\longleftrightarrow} I_r$  or not.

21 **Step 1.** Compute  $R(I_b)$  and  $R(I_r)$ . Return “no” if  $R(I_b) \neq R(I_r)$ ; otherwise  
 22 go to Step 2.

23 **Step 2.** Delete the vertices in  $N[T, R(I_b)] = N[T, R(I_r)]$  from  $T$ , and ob-  
 24 tain a forest  $F$  consisting of  $q$  trees  $T_1, T_2, \dots, T_q$ . Return “yes” if  
 25  $|I_b \cap T_j| = |I_r \cap T_j|$  holds for every  $j \in \{1, 2, \dots, q\}$ ; otherwise return  
 26 “no.”

27 We now show that our algorithm above runs in  $O(n)$  time. Clearly, Step 2  
 28 can be done in  $O(n)$  time, and hence we will show that Step 1 can be executed  
 29 in  $O(n)$  time.

30 We first give the following property of rigid tokens on a tree, which says that  
 31 deleting movable tokens does not affect the rigidity of the other tokens.

Figure 7: Illustration for Lemma 3.

1 **Lemma 3.** *Let  $I$  be an independent set of a tree  $T$ . Assume that the token on*  
2 *a vertex  $x \in I$  is  $(T, I)$ -movable. Then, for every vertex  $u \in I \setminus \{x\}$ , the token*  
3 *on  $u$  is  $(T, I)$ -rigid if and only if it is  $(T, I \setminus \{x\})$ -rigid.*

4 **PROOF.** The if direction is trivially true, because we cannot make a rigid to-  
5 ken movable by adding another token. We thus show the only-if direction by  
6 contradiction.

7 Let  $I' = I \setminus \{x\}$ . Suppose that  $u \in I$  is a closest vertex to  $x$  such that its  
8 token is  $(T, I)$ -rigid but  $(T, I')$ -movable. Let  $v$  be the neighbor of  $u$  such that  
9 the subtree  $T_v^u$  contains  $x$ . (See Figure 7.) Note that  $x \neq v$  since  $x, u \in I$   
10 and  $v$  is a neighbor of  $u$ . Since the token  $t_u$  on  $u$  is  $(T, I)$ -rigid, by Lemma 1  
11 the vertex  $v \in N(T, u)$  has at least one neighbor  $w \in I \cap N(T_v^u, v)$  such that  
12 the token  $t_w$  on  $w$  is  $(T_w^v, I \cap T_w^v)$ -rigid. Indeed,  $t_w$  is  $(T, I)$ -rigid, because  $t_u$   
13 is assumed to be  $(T, I)$ -rigid. Thus, we know that  $x \neq w$  since the token  $t_x$  on  $x$   
14 is  $(T, I)$ -movable.

15 First, consider the case where  $x$  is contained in a subtree  $T_{w'}^v$  for some  
16 neighbor  $w'$  of  $v$  other than  $w$ . (See Figure 7(a).) Then,  $I' \cap T_w^v = I \cap T_w^v$ . Since  
17  $t_w$  is  $(T_w^v, I \cap T_w^v)$ -rigid, it is also  $(T_w^v, I' \cap T_w^v)$ -rigid. Therefore, by Lemma 1  
18 the token  $t_u$  is  $(T, I')$ -rigid. This contradicts the assumption that  $t_u$  is  $(T, I')$ -  
19 movable.

20 We thus consider the case where  $x \in V(T_w^v) \setminus \{w\}$ . (See Figure 7(b).) Recall  
21 that  $I'$  is obtained by deleting only  $x$  from  $I$ . Then, since  $t_u$  is  $(T, I)$ -rigid but  
22  $(T, I')$ -movable, there must exist a reconfiguration sequence such that the token  
23  $t_u$  slides and its first slide is from  $u$  to  $v$ . However, before executing this token-  
24 slide, we have to slide  $t_w$  to some vertex in  $N(T_w^v, w)$ . Thus,  $t_w$  is  $(T_w^v, I' \cap T_w^v)$ -  
25 movable, and hence it is also  $(T, I')$ -movable. Since  $t_w$  is  $(T, I)$ -rigid and  $w$  is  
26 strictly closer to  $x \in V(T_w^v)$  than  $u$ , this contradicts the assumption that  $u$  is a  
27 closest vertex to  $x$  such that its token is  $(T, I)$ -rigid but  $(T, I')$ -movable.  $\square$

28 Then, the following lemma proves that Step 1 can be executed in  $O(n)$  time.

29 **Lemma 4.** *For an independent set  $I$  of a tree  $T$  with  $n$  vertices,  $R(I)$  can be*  
30 *computed in  $O(n)$  time.*

31 **PROOF.** Lemma 3 implies that the set  $R(I)$  of all  $(T, I)$ -rigid tokens in  $I$  can be  
32 found by removing all  $(T, I)$ -movable tokens in  $I$ . Observe that, if  $I$  contains  
33  $(T, I)$ -movable tokens, then at least one of them can be immediately slid to

1 one of its neighbors. That is, there is a token on  $u \in I$  which has a neighbor  
 2  $w \in N(T, u)$  such that  $N(T, w) \cap I = \{u\}$ . Then, the following algorithm  
 3 efficiently finds and removes such tokens iteratively.

4 **Step A.** Define and compute  $\deg_I(w) = |N(T, w) \cap I|$  for all vertices  $w \in$   
 5  $V(T)$ .

6 **Step B.** Define and compute  $M = \{u \in I \mid \exists w \in N(T, u) \text{ such that } \deg_I(w) =$   
 7  $1\}$ , that is,  $M$  is the set of tokens that can be immediately slid.

8 **Step C.** Repeat the following steps (i)–(iii) until  $M = \emptyset$ .

9 (i) Select an arbitrary vertex  $u \in M$ , and remove it from  $M$  and  
 10  $I$ .

11 (ii) Update  $\deg_I(w) := \deg_I(w) - 1$  for each neighbor  $w \in N(T, u)$ .

12 (iii) If  $\deg_I(w)$  becomes one by the update (ii) above, then add  
 13 the vertex  $u' \in N(T, w) \cap I$  into  $M$ .

14 **Step D.** Output  $I$ . Note that, since  $M = \emptyset$ , all tokens in  $I$  are now  $(T, I)$ -  
 15 rigid.

16 Clearly, Steps A, B and D can be done in  $O(n)$  time. We now show that  
 17 Step C takes only  $O(n)$  time. Each vertex in  $I$  can be selected at most once as  
 18  $u$  at Step C-(i). For the selected vertex  $u$ , Step C-(ii) takes  $O(\deg_T(u))$  time for  
 19 updating  $\deg_I(w)$  of its neighbors  $w \in N(T, u)$ . Each vertex in  $V(T) \setminus I$  can be  
 20 selected at most once as  $w$  at Step C-(iii). For the selected vertex  $w$ , Step C-(iii)  
 21 takes  $O(\deg_T(w))$  time for finding  $u' \in N(T, w) \cap I$ . Therefore, Step C takes  
 22  $O\left(\sum_{v \in V(T)} \deg_T(v)\right) = O(n)$  time in total.  $\square$

23 Therefore, Step 1 of our algorithm can be done in  $O(n)$  time, and hence the  
 24 algorithm runs in linear time in total.

### 25 3.3. Correctness of the algorithm

26 In this subsection, we prove that the  $O(n)$ -time algorithm in Section 3.2  
 27 correctly determines whether  $I_b \overset{T}{\rightsquigarrow} I_r$  or not, for two given independent sets  $I_b$   
 28 and  $I_r$  of a tree  $T$ .

29 We first show the correctness of Step 1.

30 **Observation 1.** Suppose that  $R(I_b) \neq R(I_r)$  for two given independent sets  $I_b$   
 31 and  $I_r$  of a tree  $T$ . Then, it is a no-instance.

32 **PROOF.** By the definition of rigid tokens,  $R(I_b) = R(I')$  holds for any inde-  
 33 pendent set  $I'$  of  $T$  such that  $I_b \overset{T}{\rightsquigarrow} I'$ . Therefore, there is no reconfiguration  
 34 sequence between  $I_b$  and  $I_r$  if  $R(I_r) \neq R(I_b)$ .  $\square$

35 We then show the correctness of Step 2. We first claim that deleting the  
 36 vertices with rigid tokens together with their neighbors does not affect the re-  
 37 configurability.

1 **Lemma 5.** *Suppose that  $R(I_b) = R(I_r)$  for two given independent sets  $I_b$  and*  
2  *$I_r$  of a tree  $T$ , and let  $F$  be the forest obtained by deleting the vertices in*  
3  *$N[T, R(I_b)] = N[T, R(I_r)]$  from  $T$ . Then,  $I_b \overset{T}{\rightsquigarrow} I_r$  if and only if  $I_b \cap F \overset{F}{\rightsquigarrow} I_r \cap F$ .*  
4 *Furthermore, all tokens in  $I_b \cap F$  are  $(F, I_b \cap F)$ -movable, and all tokens in  $I_r \cap F$*   
5 *are  $(F, I_r \cap F)$ -movable.*

6 **PROOF.** We first prove the if direction. Suppose that  $I_b \cap F \overset{F}{\rightsquigarrow} I_r \cap F$ , and hence  
7 there exists a reconfiguration sequence  $\mathcal{S}_F$  between  $I_b \cap F$  and  $I_r \cap F$ . Then,  
8 for each independent set  $I \in \mathcal{S}_F$  of  $F$ , the **vertex subset**  $R(I_b) \cup I = R(I_r) \cup I$   
9 forms an independent set of  $T$  since  $F$  is obtained by deleting all vertices in  
10  $N[T, R(I_b)] = N[T, R(I_r)]$ . Therefore,  $\mathcal{S}_F$  can be extended to a reconfiguration  
11 sequence between  $I_b$  and  $I_r$  of  $T$ . We thus have  $I_b \overset{T}{\rightsquigarrow} I_r$ .

12 We then prove the only-if direction. Suppose that  $I_b \overset{T}{\rightsquigarrow} I_r$ , and hence  
13 there exists a reconfiguration sequence  $\mathcal{S}_T$  between  $I_b$  and  $I_r$ . Then, for any  
14 independent set  $I \in \mathcal{S}_T$ , we have  $I_b \overset{T}{\rightsquigarrow} I$  and  $I \overset{T}{\rightsquigarrow} I_r$ , and hence by the  
15 definition of rigid tokens  $R(I_b) = R(I_r) \subseteq I$  holds. Furthermore,  $I \setminus R(I_b) =$   
16  $I \setminus R(I_r)$  is a **vertex subset** of  $V(F)$  since no token can be placed on any neighbor  
17 of  $R(I_b) = R(I_r)$ . Therefore,  $I \setminus R(I_b) = I \setminus R(I_r)$  forms an independent set of  $F$ .  
18 For two consecutive independent sets  $I_{i-1}$  and  $I_i$  in  $\mathcal{S}_T$ , let  $I_{i-1} \setminus I_i = \{u\}$  and  
19  $I_i \setminus I_{i-1} = \{v\}$ . Since  $u \notin I_i$  and  $v \notin I_{i-1}$ , neither  $u$  nor  $v$  are in  $R(I_b) = R(I_r)$ .  
20 Therefore, we have  $u, v \in V(F)$ , and hence the edge  $\{u, v\}$  is in  $E(F)$ . Then,  
21 we can obtain a reconfiguration sequence between  $I_b \cap F$  and  $I_r \cap F$  by replacing  
22 all independent sets  $I \in \mathcal{S}_T$  with  $I \cap F$ . We thus have  $I_b \cap F \overset{F}{\rightsquigarrow} I_r \cap F$ .

23 We finally prove that all tokens in  $I_b \cap F$  are  $(F, I_b \cap F)$ -movable. (The  
24 proof for the tokens in  $I_r \cap F$  is the same.) Notice that each token  $t$  on a vertex  
25  $v$  in  $I_b \cap F$  is  $(T, I_b)$ -movable; otherwise  $t \in R(I_b)$ . Therefore, there exists an  
26 independent set  $I'$  of  $T$  such that  $v \notin I'$  and  $I_b \overset{T}{\rightsquigarrow} I'$ . Then,  $I_b \cap F \overset{F}{\rightsquigarrow} I' \cap F$   
27 as we have proved above, and hence  $t$  is  $(F, I_b \cap F)$ -movable.  $\square$

28 Suppose that  $R(I_b) = R(I_r)$  for two given independent sets  $I_b$  and  $I_r$  of a  
29 tree  $T$ . Let  $F$  be the forest consisting of  $q$  trees  $T_1, T_2, \dots, T_q$ , which is obtained  
30 from  $T$  by deleting the vertices in  $N[T, R(I_b)] = N[T, R(I_r)]$ . Since we can slide  
31 a token only along an edge of  $F$ , we clearly have  $I_b \cap F \overset{F}{\rightsquigarrow} I_r \cap F$  if and only  
32 if  $I_b \cap T_j \overset{T_j}{\rightsquigarrow} I_r \cap T_j$  for all  $j \in \{1, 2, \dots, q\}$ . Furthermore, Lemma 5 implies  
33 that, for each  $j \in \{1, 2, \dots, q\}$ , all tokens in  $I_b \cap T_j$  are  $(T_j, I_b \cap T_j)$ -movable;  
34 similarly, all tokens in  $I_r \cap T_j$  are  $(T_j, I_r \cap T_j)$ -movable.

35 We now give our second key lemma, which completes the correctness proof  
36 of our algorithm.

37 **Lemma 6.** *Let  $I_b$  and  $I_r$  be two independent sets of a tree  $T$  such that all*  
38 *tokens in  $I_b$  and  $I_r$  are  $(T, I_b)$ -movable and  $(T, I_r)$ -movable, respectively. Then,*  
39  *$I_b \overset{T}{\rightsquigarrow} I_r$  if and only if  $|I_b| = |I_r|$ .*

40 The only-if direction of Lemma 6 is trivial, and hence we prove the if direc-  
41 tion. In our proof, we do *not* reconfigure  $I_b$  into  $I_r$  directly, but reconfigure both

Figure 8: A degree-1 vertex  $v$  of a tree  $T$  which is safe.

1  $I_b$  and  $I_r$  into some independent set  $I^*$  of  $T$ . Note that, since any reconfiguration  
 2 sequence is reversible,  $I_b \xleftrightarrow{T} I^*$  and  $I_r \xleftrightarrow{T} I^*$  imply that  $I_b \xleftrightarrow{T} I_r$ .

3 We say that a degree-1 vertex  $v$  of  $T$  is *safe* if its unique neighbor  $u$  has at  
 4 most one neighbor  $w$  of degree more than one. (See Figure 8.) Note that any  
 5 tree has at least one safe degree-1 vertex.

6 As the first step of the if direction proof, we give the following lemma.

7 **Lemma 7.** *Let  $I$  be an independent set of a tree  $T$  such that all tokens in  $I$  are*  
 8  *$(T, I)$ -movable, and let  $v$  be a safe degree-1 vertex of  $T$ . Then, there exists an*  
 9 *independent set  $I'$  such that  $v \in I'$  and  $I \xleftrightarrow{T} I'$ .*

10 **PROOF.** Suppose that  $v \notin I$ ; otherwise the lemma clearly holds. We will show  
 11 that one of the closest tokens from  $v$  can be slid to  $v$ . Let  $M = \{w \in I \mid$   
 12  $\text{dist}(v, w) = \min_{x \in I} \text{dist}(v, x)\}$ . Let  $w$  be an arbitrary vertex in  $M$ , and let  
 13  $(p_0 = v, p_1, \dots, p_\ell = w)$  be the  $vw$ -path in  $T$ . (See Figure 9.) If  $\ell = 1$  and hence  
 14  $p_1 \in I$ , then we can simply slide the token on  $p_1$  to  $v$ . Thus, we may assume  
 15 that  $\ell \geq 2$ .

16 We note that no token is placed on the vertices  $p_0, \dots, p_{\ell-1}$  and the neighbors  
 17 of  $p_0, \dots, p_{\ell-2}$ , because otherwise the token on  $w$  is not closest to  $v$ . Let  $M' =$   
 18  $M \cap N(T, p_{\ell-1})$ . Since  $p_{\ell-1} \notin I$ , by Lemma 2 there exists at most one vertex  
 19  $w' \in M'$  such that the token on  $w'$  is  $(T_{w'}^{p_{\ell-1}}, I \cap T_{w'}^{p_{\ell-1}})$ -rigid. We choose such  
 20 a vertex  $w'$  if it exists, otherwise choose an arbitrary vertex in  $M'$  and regard  
 21 it as  $w'$ .

22 Since all tokens on the vertices  $w''$  in  $M' \setminus \{w'\}$  are  $(T_{w''}^{p_{\ell-1}}, I \cap T_{w''}^{p_{\ell-1}})$ -movable,  
 23 we first slide the tokens on  $w''$  to some vertices in  $T_{w''}^{p_{\ell-1}}$ . Then, we can slide

Figure 9: Illustration for Lemma 7.

Figure 10: Illustration for Lemma 8.

1 the token on  $w'$  to  $v$  ( $= p_0$ ) along the path  $(w', p_{\ell-1}, p_{\ell-2}, \dots, p_0)$ . In this way,  
 2 we can obtain an independent set  $I'$  such that  $v \in I'$  and  $I \overset{T}{\rightsquigarrow} I'$ .  $\square$

3 We then prove that deleting a safe degree-1 vertex with a token together  
 4 with its neighbor does not affect the movability of the other tokens. (See also  
 5 Figure 10.)

6 **Lemma 8.** *Let  $v$  be a safe degree-1 vertex of a tree  $T$ , and let  $\bar{T}$  be the subtree  
 7 of  $T$  obtained by deleting  $v$ , its unique neighbor  $u$ , and the resulting isolated  
 8 vertices. Let  $I$  be an independent set of  $T$  such that  $v \in I$  and all tokens are  
 9  $(T, I)$ -movable. Then, all tokens in  $I \setminus \{v\}$  are  $(\bar{T}, I \setminus \{v\})$ -movable.*

10 **PROOF.** Since  $T_v^u$  consists of a single vertex  $v$ , the token on  $v$  is  $(T_v^u, I \cap T_v^u)$ -  
 11 rigid. Therefore, no token is placed on degree-1 neighbors of  $u$  other than  $v$  (see  
 12 Figure 10), because otherwise it contradicts to Lemma 2; recall that all tokens  
 13 in  $I$  are assumed to be  $(T, I)$ -movable.

14 Let  $\bar{I} = I \setminus \{v\}$ . Suppose for a contradiction that there exists a token in  $\bar{I}$   
 15 which is  $(\bar{T}, \bar{I})$ -rigid. Let  $w_p \in \bar{I}$  be such a vertex closest to  $v$ , and let  $z$  be the  
 16 vertex on the  $vw_p$ -path right before  $w_p$ .

17 **Case (1):**  $z = u$ . (See Figure 10(a).)

18 Recall that the token on  $v$  is  $(T, I)$ -movable, but is  $(T_v^u, I \cap T_v^u)$ -rigid. There-  
 19 fore, by Lemma 2 the token on  $w_p$  must be  $(T_{w_p}^u, I \cap T_{w_p}^u)$ -movable. However,  
 20 this contradicts the assumption that  $w_p$  is  $(\bar{T}, \bar{I})$ -rigid, because  $\bar{T} = T_{w_p}^u$  and  
 21  $\bar{I} = I \cap T_{w_p}^u$  in this case.

22 **Case (2):**  $z \neq u$ . (See Figure 10(b).)

23 Let  $w_1$  be the neighbor of  $z$  on the  $vw_p$ -path other than  $w_p$ ; let  $N(T, z) =$   
 24  $\{w_1, w_2, \dots, w_p\}$ . We note that the subtree  $T_{w_1}^z$  contains the deleted star  $T \setminus \bar{T}$   
 25 centered at  $u$ .

26 We first note that the token  $t_p$  on  $w_p$  is  $(\bar{T}_{w_p}^z, \bar{I} \cap \bar{T}_{w_p}^z)$ -rigid, because otherwise  
 27  $t_p$  can be slid to some vertex in  $\bar{T}_{w_p}^z$  and hence it is  $(\bar{T}, \bar{I})$ -movable. Since  
 28  $\bar{T}_{w_p}^z = T_{w_p}^z$  and  $\bar{I} \cap \bar{T}_{w_p}^z = I \cap T_{w_p}^z$ , the token  $t_p$  is also  $(T_{w_p}^z, I \cap T_{w_p}^z)$ -rigid.

29 For each  $j \in \{2, 3, \dots, p-1\}$  with  $w_j \in I$ , since  $t_p$  is  $(T_{w_p}^z, I \cap T_{w_p}^z)$ -rigid  
 30 and all tokens in  $I$  are  $(T, I)$ -movable, by Lemma 2 each token  $t_j$  on  $w_j$  is

1  $(T_{w_j}^z, I \cap T_{w_j}^z)$ -movable. Then, since  $T_{w_j}^z = \bar{T}_{w_j}^z$  and  $I \cap T_{w_j}^z = \bar{I} \cap \bar{T}_{w_j}^z$ , the  
2 token  $t_j$  is  $(\bar{T}_{w_j}^z, \bar{I} \cap \bar{T}_{w_j}^z)$ -movable. Therefore, if  $w_1 \notin \bar{I}$  or the token  $t_1$  on  $w_1$  is  
3  $(\bar{T}_{w_1}^z, \bar{I} \cap \bar{T}_{w_1}^z)$ -movable, then we can slide  $t_p$  from  $w_p$  to  $z$  after sliding each token  
4  $t_j$  in  $\bar{I} \cap \{w_1, w_2, \dots, w_{p-1}\}$  to some vertex of the subtree  $\bar{T}_{w_j}^z$ . This contradicts  
5 the assumption that  $t_p$  is  $(\bar{T}, \bar{I})$ -rigid.

6 Therefore, we have  $w_1 \in \bar{I}$  and a token  $t_1$  on  $w_1$  is  $(\bar{T}_{w_1}^z, \bar{I} \cap \bar{T}_{w_1}^z)$ -rigid.  
7 **Then,  $t_1$  is  $(\bar{T}, \bar{I})$ -rigid, because  $t_1$  can be slid only to  $z$  which is adjacent with**  
8  **$w_p$  having the  $(\bar{T}_{w_p}^z, \bar{I} \cap \bar{T}_{w_p}^z)$ -rigid token  $t_p$ .** Since  $w_1$  is on the  $vw_p$ -path in  $T$ ,  
9 this contradicts the assumption that  $t_p$  is the  $(\bar{T}, \bar{I})$ -rigid token closest to  $v$ .  $\square$

10 *Proof of the if direction of Lemma 6*

11 We now prove the if direction of the lemma by **induction** on the number of  
12 tokens  $|I_b| = |I_r|$ . The lemma clearly holds for any tree  $T$  if  $|I_b| = |I_r| = 1$ ,  
13 because  $T$  has only one token and hence we can slide it along the unique path  
14 in  $T$ .

15 We choose an arbitrary safe degree-1 vertex  $v$  of a tree  $T$ , whose unique  
16 neighbor is  $u$ . Since all tokens in  $I_b$  are  $(T, I_b)$ -movable, by Lemma 7 we can  
17 obtain an independent set  $I'_b$  of  $T$  such that  $v \in I'_b$  and  $I_b \overset{T}{\longleftrightarrow} I'_b$ . By Lemma 8  
18 all tokens in  $I'_b \setminus \{v\}$  are  $(\bar{T}, I'_b \setminus \{v\})$ -movable, where  $\bar{T}$  is the subtree defined  
19 in Lemma 8. Similarly, we can obtain an independent set  $I'_r$  of  $T$  such that  
20  $v \in I'_r$ ,  $I_r \overset{T}{\longleftrightarrow} I'_r$  and all tokens in  $I'_r \setminus \{v\}$  are  $(\bar{T}, I'_r \setminus \{v\})$ -movable. Apply  
21 the induction hypothesis to the pair of independent sets  $I'_b \setminus \{v\}$  and  $I'_r \setminus \{v\}$   
22 of  $\bar{T}$ . Then, we have  $I'_b \setminus \{v\} \overset{\bar{T}}{\longleftrightarrow} I'_r \setminus \{v\}$ . Recall that both  $u \notin I'_b$  and  
23  $u \notin I'_r$  hold, and  $u$  is the unique neighbor of  $v$  in  $T$ . Furthermore,  $u \notin V(\bar{T})$ .  
24 Therefore, we can extend the reconfiguration sequence in  $\bar{T}$  between  $I'_b \setminus \{v\}$   
25 and  $I'_r \setminus \{v\}$  to a reconfiguration sequence in  $T$  between  $I'_b$  and  $I'_r$ . We thus have  
26  $I_b \overset{T}{\longleftrightarrow} I'_b \overset{T}{\longleftrightarrow} I'_r \overset{T}{\longleftrightarrow} I_r$ .

27 This completes the proof of Lemma 6, and hence completes the proof of  
28 Theorem 1.  $\square$

### 29 3.4. Length of reconfiguration sequence

30 In this subsection, we show that an actual reconfiguration sequence can be  
31 found for a yes-instance on trees, by implementing our proofs in Section 3.3.  
32 Furthermore, the length of the obtained reconfiguration sequence is at most  
33 quadratic.

34 **Theorem 2.** *Let  $I_b$  and  $I_r$  be two independent sets of a tree  $T$  with  $n$  vertices.*  
35 *If  $I_b \overset{T}{\longleftrightarrow} I_r$ , then there exists a reconfiguration sequence of length  $O(n^2)$  between*  
36  *$I_b$  and  $I_r$ , and it can be output in  $O(n^2)$  time.*

37 **As we have mentioned in Introduction, recall that** there exists an infinite family  
38 of instances on paths for which any reconfiguration sequence requires  $\Omega(n^2)$   
39 length, where  $n$  is the number of vertices.

1 We note that a reconfiguration sequence  $\mathcal{S}$  can be represented by a sequence  
 2 of edges on which tokens are slid. Therefore, the space for representing  $\mathcal{S}$  can  
 3 be bounded by a **function** linear in the length of  $\mathcal{S}$ .

4 By Theorem 1 we can determine whether  $I_b \overset{T}{\rightsquigarrow} I_r$  or not in  $O(n)$  time. In the  
 5 following, we thus assume that  $I_b \overset{T}{\rightsquigarrow} I_r$ . Furthermore, suppose that all tokens  
 6 in  $I_b$  are  $(T, I_b)$ -movable, and that all tokens in  $I_r$  are  $(T, I_r)$ -movable; otherwise  
 7 we obtain the forest by deleting the vertices in  $N[T, \mathbf{R}(I_b)] = N[T, \mathbf{R}(I_r)]$  from  
 8  $T$ , and find a reconfiguration sequence for each tree in the forest, according to  
 9 Lemma 5.

10 As in the if-direction proof of Lemma 6, we choose an arbitrary safe degree-  
 11 1 vertex  $v$  of  $T$ , and obtain an independent set  $I'_b$  of  $T$  such that  $v \in I'_b$  and  
 12  $I_b \overset{T}{\rightsquigarrow} I'_b$ , as follows.

- 13 (a) Find a vertex  $w \in I_b$  which is closest to  $v$ , and let  $(v, p_1, p_2, \dots, p_{\ell-1}, w)$   
 14 be the  $vw$ -path in  $T$ . Let  $M' = I_b \cap N(T, p_{\ell-1})$ . (See also Figure 9.)
- 15 (b) Choose a vertex  $w'$  such that the token on  $w'$  is  $(T_{w'}^{p_{\ell-1}}, I \cap T_{w'}^{p_{\ell-1}})$ -rigid if  
 16 it exists, otherwise choose an arbitrary vertex in  $M'$  and regard it as  $w'$ .
- 17 (c) Slide each token on  $w'' \in M' \setminus \{w'\}$  to some vertex in  $T_{w''}^{p_{\ell-1}}$ , and then  
 18 slide the token on  $w'$  to  $v$ .

19 In Lemma 7 we have proved that such a reconfiguration sequence from  $I_b$  to  $I'_b$   
 20 always exists. We apply the same process to  $I_r$  **for the same safe degree-1 vertex**  
 21  **$v$ , and obtain an independent set  $I'_r$  of  $T$  such that  $I_r \overset{T}{\rightsquigarrow} I'_r$  and  $v \in I'_b \cap I'_r$ .**  
 22 Repeat these processes until we obtain the same independent set  $I^*$  of  $T$  such  
 23 that  $I_b \overset{T}{\rightsquigarrow} I^*$  and  $I_r \overset{T}{\rightsquigarrow} I^*$ . Note that, since any reconfiguration sequence is  
 24 reversible, this means that we obtained a reconfiguration sequence between  $I_b$   
 25 and  $I_r$ .

26 Therefore, to prove Theorem 2, it suffices to show that the algorithm above  
 27 runs in  $O(n)$  time for one safe degree-1 vertex  $v$  and the reconfiguration sequence  
 28 for sliding one token to  $v$  is of length  $O(n)$ . In particular, the following lemma  
 29 completes the proof of Theorem 2.

30 **Lemma 9.** *Let  $I$  be an independent set of a tree  $T$ , and let  $w \in I$ . For a*  
 31 *neighbor  $z \in N(T, w)$ , suppose that the token on  $w$  is  $(T_w^z, I \cap T_w^z)$ -movable.*  
 32 *Then, there exists a reconfiguration sequence  $\mathcal{S}_w$  of length at most  $|V(T_w^z)|$  from*  
 33  *$I$  to an independent set  $I'$  of  $T$  such that  $w \notin I'$  and  $J \cap (T \setminus T_w^z) = I \cap (T \setminus T_w^z)$*   
 34 *for all  $J \in \mathcal{S}_w$ . Furthermore,  $\mathcal{S}_w$  can be output in  $O(|V(T_w^z)|)$  time.*

35 **PROOF.** We prove the lemma by **induction** on the depth of  $T_w^z$ , where the depth  
 36 of a tree is the longest distance from its root to a leaf. If the depth of  $T_w^z$   
 37 is zero (and hence  $T_w^z$  consists of a single vertex  $w$ ), then the token on  $w$  is  
 38  $(T_w^z, I \cap T_w^z)$ -rigid; this contradicts the assumption. Therefore, we may assume  
 39 that the depth is at least one. If the depth of  $T_w^z$  is exactly one, then  $T_w^z$  is a  
 40 star centered at  $w$ , and no token is placed on any neighbor of  $w$ . Thus, we can  
 41 slide the token on  $w$  by 1 ( $< |V(T_w^z)|$ ) token-slides. Then, the lemma holds for  
 42 trees  $T_w^z$  with depth one.

43 Assume that the depth of  $T_w^z$  is  $k \geq 2$ , and that the lemma holds for trees  
 44 with depth at most  $k - 1$ . Since  $w$  is  $(T_w^z, I \cap T_w^z)$ -movable, by Lemma 1 there

Figure 11: Illustration for Lemma 9.

1 is a vertex  $y \in N(T_w^z, w)$  such that either  $I \cap N(T_y^w, y) = \emptyset$  or all tokens on the  
 2 vertices  $x$  in  $I \cap N(T_y^w, y)$  are  $(T_x^y, I \cap T_x^y)$ -movable. (See Figure 11.) Then,  
 3 we can obtain a reconfiguration sequence which (1) first slides all tokens on the  
 4 vertices  $x$  in  $I \cap N(T_y^w, y)$  to some vertices in  $T_x^y$  if  $I \cap N(T_y^w, y) \neq \emptyset$ , and (2)  
 5 then slide the token on  $w$  to the vertex  $y$ . By applying the induction hypothesis  
 6 to each subtree  $T_x^y$ , this reconfiguration sequence is of length at most

$$1 + \sum_{x \in I \cap N(T_y^w, y)} |V(T_x^y)| = |V(T_y^w)|,$$

7 and can be output in  $O(|V(T_y^w)|)$  time. Note that  $w \notin I'$  holds for the obtained  
 8 independent set  $I'$  of  $T$ . Thus, the lemma holds for trees  $T_w^z$  with depth  $k$ .  $\square$

9 **We note that this lemma does not yield a reconfiguration sequence with the**  
 10 **shortest length between  $I_b$  and  $I_r$ ; such a reconfiguration sequence may not use**  
 11 **any safe degree-1 vertex.**

#### 12 4. Concluding Remarks

13 In this paper, we have developed an  $O(n)$ -time algorithm to solve the SLID-  
 14 ING TOKEN problem for trees with  $n$  vertices, based on a simple but non-trivial  
 15 characterization of rigid tokens. We have shown that there exists a reconfig-  
 16 uration sequence of length  $O(n^2)$  for any yes-instance on trees, and it can be  
 17 output in  $O(n^2)$  time. Furthermore, there exists an infinite family of instances  
 18 on paths for which any reconfiguration sequence requires  $\Omega(n^2)$  length.

19 The complexity status of SLIDING TOKEN remains open for chordal graphs  
 20 and interval graphs. Interestingly, these graphs have no-instances such that all  
 21 tokens are movable. (See Figure 12 for example.)

Figure 12: No-instance for an interval graph such that all tokens are movable.
